INTRODUCTION

Squirrel is a high-level, imperative-OO programming language, designed to be a powerful scripting tool that fits within the size, memory bandwidth, and real-time requirements of applications like games. Squirrel offers a wide range of features like dynamic typing, delegation, higher order functions, generators, tail recursion, exception handling, automatic memory management while fitting both compiler and virtual machine into about 6k lines of C++ code.

THE LANGUAGE

2.1 Lexical Structure

2.1.1 Identifiers

Identifiers start with an alphabetic character or the symbol ‘_’ followed by any number of alphabetic characters, ‘_’ or digits ([0-9]). Squirrel is a case sensitive language meaning that the lowercase and uppercase representation of the same alphabetic character are considered different characters. For instance, “foo”, “Foo” and “fOo” are treated as 3 distinct identifiers.

2.1.2 Keywords

The following words are reserved and cannot be used as identifiers:

base	break	case	catch	class	clone
continue	const	default	delete	else	enum
extends	for	foreach	function	if	in
local	null	resume	return	switch	this
throw	try	typeof	while	yield	constructor
instanceof	true	false	static	__LINE__	__FILE__
rawcall					

Keywords are covered in detail later in this document.

2.1.3 Operators

Squirrel recognizes the following operators:

!	!=		==	&&	>=	<=	>
<=>	+	+=	-	-=	/	/=	*
*=	%	%=	++	--	<-	=	&
^		~	>>	<<	>>>		

2.1.4 Other tokens

Other significant tokens are:

{	}	[]	.	:
::	'	;	"	@	"

2.1.5 Literals

Squirrel accepts integer numbers, floating point numbers and string literals.

34	Integer number(base 10)
0xFF00A120	Integer number(base 16)
0753	Integer number(base 8)
'a'	Integer number
1.52	Floating point number
1.e2	Floating point number
1.e-2	Floating point number
"I'm a string"	String
@"I'm a verbatim string"	String
@" I'm a multiline verbatim string "	String

Pesudo BNF

```
IntegerLiteral ::= [1-9][0-9]* | '0x' [0-9A-Fa-f]+ | ''' [.]+ ''' | 0[0-7]+
FloatLiteral ::= [0-9]+ '.' [0-9]+
FloatLiteral ::= [0-9]+ '.' 'e'|'E' '+'|'-' [0-9]+
StringLiteral ::= ''' [.]* '''
VerbatimStringLiteral ::= '@'''' [.]* '''
```

2.1.6 Comments

A comment is text that the compiler ignores but that is useful for programmers. Comments are normally used to embed annotations in the code. The compiler treats them as white space.

A comment can be /* (slash, asterisk) characters, followed by any sequence of characters (including new lines), followed by the */ characters. This syntax is the same as ANSI C.:

```
/*
this is
a multiline comment.
this lines will be ignored by the compiler
*/
```

A comment can also be // (two slashes) characters, followed by any sequence of characters. A new line not immediately preceded by a backslash terminates this form of comment. It is commonly called a “*single-line comment*.”:

```
//this is a single line comment. this line will be ignored by the compiler
```

The character # is an alternative syntax for single line comment.:

```
# this is also a single line comment.
```

This to facilitate the use of squirrel in UNIX-style shell scripts.

2.2 Values and Data types

While Squirrel is a dynamically typed language and variables do not have a type, different operations may interpret the variable as containing a type. Squirrel's basic types are integer, float, string, null, table, array, function, generator, class, instance, bool, thread and userdata.

2.2.1 Integer

An Integer represents a 32 bit (or better) signed number.:

```
local a = 123 //decimal
local b = 0x0012 //hexadecimal
local c = 075 //octal
local d = 'w' //char code
```

2.2.2 Float

A float represents a 32 bit (or better) floating point number.:

```
local a=1.0
local b=0.234
```

2.2.3 String

Strings are an immutable sequence of characters. In order to modify a string is it necessary create a new one.

Squirrel's strings are similar to strings in C or C++. They are delimited by quotation marks(") and can contain escape sequences (\t, \a, \b, \n, \r, \v, \f, \\, \", \', \0, \x<hh>, \u<hhhh> and \U<hhhhhhhh>).

Verbatim string literals do not interpret escape sequences. They begin with @" and end with the matching quote. Verbatim string literals also can extend over a line break. If they do, they include any white space characters between the quotes:

```
local a = "I'm a wonderful string\n"
// has a newline at the end of the string
local x = @"I'm a verbatim string\n"
// the \n is literal, similar to "\\n" in a regular string.
```

However, a doubled quotation mark within a verbatim string is replaced by a single quotation mark:

```
local multiline = @"
    this is a multiline string
    it will ""embed"" all the new line
    characters
"
```

2.2.4 Null

The null value is a primitive value that represents the null, empty, or non-existent reference. The type Null has exactly one value, called null.:

```
local a = null
```

2.2.5 Bool

Bool is a double-valued (Boolean) data type. Its literals are `true` and `false`. A bool value expresses the validity of a condition (tells whether the condition is true or false):.

```
local a = true;
```

2.2.6 Table

Tables are associative containers implemented as a set of key/value pairs called slots:.

```
local t={}  
local test=  
{  
  a=10  
  b=function(a) { return a+1; }  
}
```

2.2.7 Array

Arrays are simple sequence of objects. Their size is dynamic and their index always starts from 0:.

```
local a = ["I'm", "an", "array"]  
local b = [null]  
b[0] = a[2];
```

2.2.8 Function

Functions are similar to those in other C-like languages with a few key differences (see below).

2.2.9 Class

Classes are associative containers implemented as sets of key/value pairs. Classes are created through a ‘class expression’ or a ‘class statement’. class members can be inherited from another class object at creation time. After creation, members can be added until an instance of the class is created.

2.2.10 Class Instance

Class instances are created by calling a *class object*. Instances, as tables, are implemented as sets of key/value pairs. Instance members cannot be dynamically added or removed; however the value of the members can be changed.

2.2.11 Generator

Generators are functions that can be suspended with the statement ‘yield’ and resumed later (see *Generators*).

2.2.12 Userdata

Userdata objects are blobs of memory or pointers defined by the host application but stored within Squirrel variables (See *Userdata and UserPointers*).

2.2.13 Thread

Threads are objects representing a cooperative thread of execution, also known as coroutines.

2.2.14 Weak Reference

Weak References are objects that point to another (non-scalar) object but do not own a strong reference to it. (See *Weak References*).

2.3 Execution Context

The execution context is the union of the function stack frame and the function environment object(`this`) and the function root(`root table`). The stack frame is the portion of stack where the local variables declared in its body are stored. The environment object is an implicit parameter that is automatically passed by the function caller (see *functions*). The root table is a table associated to the function during its creation. The root table value of a function is the root table of the VM at the function creation. The root table of function can also be changed after creation with `closure.setroot()`. During the execution, the body of a function can only transparently refer to his execution context. This mean that a single identifier can refer to a local variable, to an environment object slot or to the slot of the closure root table; The environment object can be explicitly accessed by the keyword `this`. The closure root table can be explicitly accessed through the operator `::` (see *Variables*).

2.3.1 Variables

There are two types of variables in Squirrel, local variables and tables/arrays slots. Because global variables(variables stored in the root of a closure) are stored in a table, they are table slots.

A single identifier refers to a local variable or a slot in the environment object.:

```
derefexp := id;
```

```
_table["foo"]  
_array[10]
```

with tables we can also use the `'.'` syntax:

```
derefexp := exp '.' id
```

```
_table.foo
```

Squirrel first checks if an identifier is a local variable (function arguments are local variables) if not looks up the environment object (`this`) and finally looks up to the closure root.

For instance::

```
function testy(arg)
{
    local a=10;
    print(a);
    return arg;
}
```

in this case 'foo' will be equivalent to 'this.foo' or this["foo"].

Global variables are stored in a table called the root table. Usually in the global scope the environment object is the root table, but to explicitly access the closure root of the function from another scope, the slot name must be prefixed with ' :: ' (::foo).

For instance::

```
function testy(arg)
{
    local a=10;
    return arg+::foo;
}
```

accesses the variable 'foo' in the closure root table.

Since Squirrel 3.1 each function has a weak reference to a specific root table, this can differ from the current VM root table.:

```
function test() {
    foo = 10;
}
```

is equivalent to write:

```
function test() {
    if("foo" in this) {
        this.foo = 10;
    } else {
        ::foo = 10;
    }
}
```

2.4 Statements

A squirrel program is a simple sequence of statements.:

```
stats := stat [';' | '\n'] stats
```

Statements in squirrel are comparable to the C-Family languages (C/C++, Java, C# etc. . .): assignment, function calls, program flow control structures etc.. plus some custom statement like yield, table and array constructors (All those will be covered in detail later in this document). Statements can be separated with a new line or ';' (or with the keywords case or default if inside a switch/case statement), both symbols are not required if the statement is followed by '}'.

2.4.1 Block

```
stat := '{' stats '}'
```

A sequence of statements delimited by curly brackets ({ }) is called block; a block is a statement itself.

2.4.2 Control Flow Statements

squirrel implements the most common control flow statements: `if`, `while`, `do-while`, `switch-case`, `for`, `foreach`

true and false

Squirrel has a boolean type (`bool`) however like C++ it considers `null`, `0`(integer) and `0.0`(float) as *false*, any other value is considered *true*.

if/else statement

```
stat:= 'if' '(' exp ')' stat ['else' stat]
```

Conditionally execute a statement depending on the result of an expression.:

```
if(a>b)
    a=b;
else
    b=a;
////
if(a==10)
{
    b=a+b;
    return a;
}
```

while statement

```
stat:= 'while' '(' exp ')' stat
```

Executes a statement while the condition is true.:

```
function testy(n)
{
    local a=0;
    while(a<n) a+=1;

    while(1)
    {
        if(a<0) break;
        a-=1;
    }
}
```

do/while statement

```
stat := 'do' stat 'while' '(' expression ')'
```

Executes a statement once, and then repeats execution of the statement until a condition expression evaluates to false.:

```
local a=0;
do
{
    print(a+"\n");
    a+=1;
} while(a>100)
```

switch statement

```
stat := 'switch' '(' exp ')' '{'
'case' case_exp ':'
    stats
['default' ':'
    stats]
}'
```

Switch is a control statement allows multiple selections of code by passing control to one of the case statements within its body. The control is transferred to the case label whose case_exp matches with exp if none of the case match will jump to the default label (if present). A switch statement can contain any number of case instances, if 2 case have the same expression result the first one will be taken in account first. The default label is only allowed once and must be the last one. A break statement will jump outside the switch block.

2.4.3 Loops

for

```
stat := 'for' '(' [initexp] ';' [condexp] ';' [incexp] ') ' statement
```

Executes a statement as long as a condition is different than false.:

```
for(local a=0;a<10;a+=1)
    print(a+"\n");
//or
glob <- null
for(glob=0;glob<10;glob+=1){
    print(glob+"\n");
}
//or
for(;;){
    print(loops forever+"\n");
}
```

foreach

```
'foreach' '(' [index_id',' value_id 'in' exp ']' stat
```

Executes a statement for every element contained in an array, table, class, string or generator. If exp is a generator it will be resumed every iteration as long as it is alive; the value will be the result of 'resume' and the index the sequence number of the iteration starting from 0.:

```
local a=[10,23,33,41,589,56]
foreach(idx,val in a)
    print("index="+idx+" value="+val+"\n");
//or
foreach(val in a)
    print("value="+val+"\n");
```

2.4.4 break

```
stat := 'break'
```

The break statement terminates the execution of a loop (for, foreach, while or do/while) or jumps out of switch statement;

2.4.5 continue

```
stat := 'continue'
```

The continue operator jumps to the next iteration of the loop skipping the execution of the following statements.

2.4.6 return

```
stat:= return [exp]
```

The return statement terminates the execution of the current function/generator and optionally returns the result of an expression. If the expression is omitted the function will return null. If the return statement is used inside a generator, the generator will not be resumable anymore.

2.4.7 yield

```
stat := yield [exp]
```

(see *Generators*).

2.4.8 Local variables declaration

```
initz := id [= exp][',' initz]
stat := 'local' initz
```

Local variables can be declared at any point in the program; they exist between their declaration to the end of the block where they have been declared. *EXCEPTION*: a local declaration statement is allowed as first expression in a for loop.:

```
for(local a=0;a<10;a+=1)
  print(a);
```

2.4.9 Function declaration

```
funcname := id ['::' id]
stat:= 'function' id ['::' id]+ '(' args ')' stat
```

creates a new function.

2.4.10 Class declaration

```
memberdecl := id '=' exp [';'] | '[' exp ']' '=' exp [';'] | functionstat |
↳ 'constructor' functionexp
stat:= 'class' derefexp ['extends' derefexp] '{'
    [memberdecl]
    '}'
```

creates a new class.

2.4.11 try/catch

```
stat:= 'try' stat 'catch' '(' id ')' stat
```

The try statement encloses a block of code in which an exceptional condition can occur, such as a runtime error or a throw statement. The catch clause provides the exception-handling code. When a catch clause catches an exception, its id is bound to that exception.

2.4.12 throw

```
stat:= 'throw' exp
```

Throws an exception. Any value can be thrown.

2.4.13 const

```
stat:= 'const' id '=' 'Integer | Float | StringLiteral
```

Declares a constant (see *Constants & Enumerations*).

2.4.14 enum

```
enumerations := ( 'id' '=' Integer | Float | StringLiteral ) [',' ]
stat:= 'enum' id '{' enumerations '}'
```

Declares an enumeration (see *Constants & Enumerations*).

2.4.15 Expression statement

```
stat := exp
```

In Squirrel every expression is also allowed as statement, if so, the result of the expression is thrown away.

2.5 Expressions

2.5.1 Assignment

```
exp := derefexp '=' exp
exp:= derefexp '<-' exp
```

squirrel implements 2 kind of assignment: the normal assignment(=):

```
a = 10;
```

and the “new slot” assignment.:

```
a <- 10;
```

The new slot expression allows to add a new slot into a table(see [Tables](#)). If the slot already exists in the table it behaves like a normal assignment.

2.5.2 Operators

?: Operator

```
exp := exp_cond '?' expl ':' exp2
```

conditionally evaluate an expression depending on the result of an expression.

Arithmetic

```
exp:= 'exp' op 'exp'
```

Squirrel supports the standard arithmetic operators +, -, *, / and %. Other than that is also supports compact operators (+=, -=, *=, /=, %=) and increment and decrement operators(++ and --);:

```
a += 2;
//is the same as writing
a = a + 2;
x++
//is the same as writing
x = x + 1
```

All operators work normally with integers and floats; if one operand is an integer and one is a float the result of the expression will be float. The + operator has a special behavior with strings; if one of the operands is a string the operator + will try to convert the other operand to string as well and concatenate both together. For instances and tables, `_toString` is invoked.

Relational

```
exp:= 'exp' op 'exp'
```

Relational operators in Squirrel are : ==, <, <=, >, >=, !=

These operators return true if the expression is false and a value different than true if the expression is true. Internally the VM uses the integer 1 as true but this could change in the future.

3 ways compare

```
exp:= 'exp' <=> 'exp'
```

the 3 ways compare operator <=> compares 2 values A and B and returns an integer less than 0 if A < B, 0 if A == B and an integer greater than 0 if A > B.

Logical

```
exp := exp op exp  
exp := '!' exp
```

Logical operators in Squirrel are : &&, ||, !

The operator && (logical and) returns null if its first argument is null, otherwise returns its second argument. The operator || (logical or) returns its first argument if is different than null, otherwise returns the second argument.

The '!' operator will return null if the given value to negate was different than null, or a value different than null if the given value was null.

in operator

```
exp:= keyexp 'in' tableexp
```

Tests the existence of a slot in a table. Returns true if *keyexp* is a valid key in *tableexp*

```
local t=  
{  
    foo="I'm foo",  
    [123]="I'm not foo"  
}  
  
if("foo" in t) dostuff("yep");  
if(123 in t) dostuff();
```

instanceof operator

```
exp:= instanceexp 'instanceof' classexp
```

Tests if a class instance is an instance of a certain class. Returns true if *instanceexp* is an instance of *classexp*.

typeof operator

```
exp:= 'typeof' exp
```

returns the type name of a value as string.:

```
local a={},b="squirrel"
print(typeof a); //will print "table"
print(typeof b); //will print "string"
```

Comma operator

```
exp:= exp ',' exp
```

The comma operator evaluates two expression left to right, the result of the operator is the result of the expression on the right; the result of the left expression is discarded.:

```
local j=0,k=0;
for(local i=0; i<10; i++ , j++)
{
    k = i + j;
}
local a,k;
a = (k=1,k+2); //a becomes 3
```

Bitwise Operators

```
exp:= 'exp' op 'exp'
exp := '~' exp
```

Squirrel supports the standard C-like bitwise operators `&`, `|`, `^`, `~`, `<<`, `>>` plus the unsigned right shift operator `>>>`. The unsigned right shift works exactly like the normal right shift operator(`>>`) except for treating the left operand as an unsigned integer, so is not affected by the sign. Those operators only work on integer values; passing of any other operand type to these operators will cause an exception.

Operators precedence

<code>-, ~, !, typeof, ++, --</code>	highest
<code>/, *, %</code>	...
<code>+, -</code>	
<code><<, >>, >>></code>	
<code><, <=, >, >=, instanceof</code>	
<code>==, !=, <=></code>	
<code>&</code>	
<code>^</code>	
<code>&&, in</code>	
<code>+=, =, -=, /=, *=, %=</code>	...
<code>,</code> (comma operator)	lowest

2.5.3 Table Constructor

```
tslots := ( 'id' '=' exp | '[' exp ']' '=' exp ) [',' ]  
exp := '{' [tslots] '}'
```

Creates a new table.:

```
local a = {} //create an empty table
```

A table constructor can also contain slots declaration; With the syntax:

```
local a = {  
    slot1 = "I'm the slot value"  
}
```

An alternative syntax can be:

```
'[' exp1 ']' = exp2 [',' ]
```

A new slot with exp1 as key and exp2 as value is created:

```
local a=  
{  
    [1]="I'm the value"  
}
```

Both syntaxes can be mixed:

```
local table=  
{  
    a=10,  
    b="string",  
    [10]={},  
    function bau(a,b)  
    {  
        return a+b;  
    }  
}
```

The comma between slots is optional.

Table with JSON syntax

Since Squirrel 3.0 is possible to declare a table using JSON syntax(see <http://www.wikipedia.org/wiki/JSON>).
the following JSON snippet:

```
local x = {  
    "id": 1,  
    "name": "Foo",  
    "price": 123,  
    "tags": ["Bar", "Eek"]  
}
```

is equivalent to the following squirrel code:

```
local x = {
  id = 1,
  name = "Foo",
  price = 123,
  tags = ["Bar", "Eek"]
}
```

2.5.4 clone

```
exp := 'clone' exp
```

Clone performs shallow copy of a table, array or class instance (copies all slots in the new object without recursion). If the source table has a delegate, the same delegate will be assigned as delegate (not copied) to the new table (see *Delegation*).

After the new object is ready the “_cloned” meta method is called (see *Metamethods*).

When a class instance is cloned the constructor is not invoked (initializations must rely on `__cloned`` instead

2.5.5 Array constructor

```
exp := '[' [explist] ']'
```

Creates a new array.:

```
a <- [] //creates an empty array
```

Arrays can be initialized with values during the construction:

```
a <- [1, "string!", [], {}] //creates an array with 4 elements
```

2.6 Tables

Tables are associative containers implemented as pairs of key/value (called slot); values can be any possible type and keys any type except ‘null’. Tables are squirrel’s skeleton, delegation and many other features are all implemented through this type; even the environment, where “global” variables are stored, is a table (known as root table).

2.6.1 Construction

Tables are created through the table constructor (see *Table constructor*)

2.6.2 Slot creation

Adding a new slot in a existing table is done through the “new slot” operator `<-`; this operator behaves like a normal assignment except that if the slot does not exists it will be created.:

```
local a = {}
```

The following line will cause an exception because the slot named ‘newslot’ does not exist in the table ‘a’:

```
a.newslot = 1234
```

this will succeed:

```
a.newslot <- 1234;
```

or:

```
a[1] <- "I'm the value of the new slot";
```

2.6.3 Slot deletion

```
exp:= delete derefexp
```

Deletion of a slot is done through the keyword `delete`; the result of this expression will be the value of the deleted slot.:

```
a <- {
  test1=1234
  deleteme="now"
}

delete a.test1
print(delete a.deleteme); //this will print the string "now"
```

2.7 Arrays

An array is a sequence of values indexed by a integer number from 0 to the size of the array minus 1. Arrays elements can be obtained through their index.:

```
local a=["I'm a string", 123]
print(typeof a[0]) //prints "string"
print(typeof a[1]) //prints "integer"
```

Resizing, insertion, deletion of arrays and arrays elements is done through a set of standard functions (see *built-in functions*).

2.8 Functions

Functions are first class values like integer or strings and can be stored in table slots, local variables, arrays and passed as function parameters. Functions can be implemented in Squirrel or in a native language with calling conventions compatible with ANSI C.

2.8.1 Function declaration

Functions are declared through the function expression:

```
local a = function(a, b, c) { return a + b - c; }
```

or with the syntactic sugar:

```
function ciao(a,b,c)
{
  return a+b-c;
}
```

that is equivalent to:

```
this.ciao <- function(a,b,c)
{
  return a+b-c;
}
```

a local function can be declared with this syntactic sugar:

```
local function tuna(a,b,c)
{
  return a+b-c;
}
```

that is equivalent to:

```
local tuna = function(a,b,c)
{
  return a+b-c;
}
```

is also possible to declare something like:

```
T <- {}
function T::ciao(a,b,c)
{
  return a+b-c;
}

//that is equivalent to write

T.ciao <- function(a,b,c)
{
  return a+b-c;
}

//or

T <- {
  function ciao(a,b,c)
  {
    return a+b-c;
  }
}
```

Default Paramaters

Squirrel's functions can have default parameters.

A function with default parameters is declared as follows:

```
function test(a,b,c = 10, d = 20)
{
    ....
}
```

when the function *test* is invoked and the parameter *c* or *d* are not specified, the VM automatically assigns the default value to the unspecified parameter. A default parameter can be any valid squirrel expression. The expression is evaluated at runtime.

Function with variable number of parameters

Squirrel's functions can have variable number of parameters (varargs functions).

A vararg function is declared by adding three dots (...) at the end of its parameter list.

When the function is called all the extra parameters will be accessible through the *array* called *vargv*, that is passed as implicit parameter.

vargv is a regular squirrel array and can be used accordingly.:

```
function test(a,b,...)
{
    for(local i = 0; i < vargv.len(); i++)
    {
        ::print("varparam "+i+" = "+vargv[i)+"\n");
    }
    foreach(i,val in vargv)
    {
        ::print("varparam "+i+" = "+val+"\n");
    }
}

test("goes in a","goes in b",0,1,2,3,4,5,6,7,8);
```

2.8.2 Function calls

```
exp:= derefexp '(' explist ')'
```

The expression is evaluated in this order: derefexp after the explist (arguments) and at the end the call.

A function call in Squirrel passes the current environment object *this* as a hidden parameter. But when the function was immediately indexed from an object, *this* shall be the object which was indexed, instead.

If we call a function with the syntax:

```
mytable.foo(x,y)
```

the environment object passed to 'foo' as *this* will be 'mytable' (since 'foo' was immediately indexed from 'mytable')

Whereas with the syntax:

```
foo(x,y) // implicitly equivalent to this.foo(x,y)
```

the environment object will be the current *this* (that is, propagated from the caller's *this*).

It may help to remember the rules in the following way:

`foo(x,y)` → `this.foo(x,y)` `table.foo(x,y)` → call `foo` with `(table,x,y)`

It may also help to consider why it works this way: it's designed to assist with object-oriented style. When calling `'foo(x,y)'` it's assumed you're calling another member of the object (or of the file) and so should operate on the same object. When calling `'mytable.foo(x,y)'` it's written plainly that you're calling a member of a different object.

2.8.3 Raw calls

It is possible to call a function overriding the default calling semantics by utilizing the keyword *rawcall*. Rawcall allows to invoke a function specifying the *this* object explicitly:

```
local retval = rawcall(functionobj,thisobj,parameters);
```

for example:

```
local env = {}
function test(a,b) {
    return a + b;
}
local ret = rawcall(test,env,1,2) //passes the table env as 'this' to the function_
↳test
```

2.8.4 Post-call Initializer

Since version 3.2 Squirrel offers a syntactic sugar to initialize the object returned by a function call (and class instance creation). The post-call initializer has the following syntax:

```
function test() {
    local retval = { x = 0, y = 0 };
    return retval;
}
local ret1 = test() { x = 10, y = 20 }
local ret2 = test() { x = 30, y = 40 }
```

that is equivalent to:

```
function test() {
    local retval = { x = 0, y = 0 };
    return retval;
}
local ret1 = test() { x = 10, y = 20 }
ret1.x = 10;
ret1.y = 20;
local ret2 = test() { x = 30, y = 40 }
ret2.x = 30;
ret2.y = 40;
```

this is also usable with classes:

```
class vector3 {
    x = 0;
    y = 0;
    z = 0;
}
```

(continues on next page)

(continued from previous page)

```
local v0 = vector3() { x = 1, y = 2, z = 3 };
local v2 = vector3() { x = 4, y = 5, z = 6 };
```

and can be nested:

```
class entity {
    position = null;
    direction = null;
}
local ret = entity() {
    position = vector3() { x = 1, y = 2, z = 3 }
    direction = vector3() { x = 0, y = 1, z = 0 }
}
```

2.8.5 Binding an environment to a function

while by default a squirrel function call passes as environment object 'this', the object where the function was indexed from. However, is also possible to statically bind an environment to a closure using the following syntax.:

```
function test[env_obj](a,b) {
    return a + b;
}

local test = function[env_obj](a,b) {
    return a + b;
}

local function test[env_obj](a,b) {
    return a + b;
}
```

It is also possible to statically bind an environment to a closure using the built-in method `closure.bindenv(env_obj)`. The method `bindenv()` returns a new instance of a closure with the environment bound to it.

When an environment object is bound to a function, every time the function is invoked, its 'this' parameter will always be the previously bound environment. This mechanism is useful to implement callbacks systems similar to C# delegates.

Note: The closure keeps a weak reference to the bound environment object, because of this if the object is deleted, the next call to the closure will result in a null environment object.

2.8.6 Lambda Expressions

```
exp := '@' '(' paramlist ')' exp
```

Lambda expressions are a syntactic sugar to quickly define a function that consists of a single expression. This feature comes handy when functional programming patterns are applied, like map/reduce or passing a compare method to `array.sort()`.

here a lambda expression:

```
local myexp = @(a,b) a + b
```

that is equivalent to:

```
local myexp = function(a,b) { return a + b; }
```

a more useful usage could be:

```
local arr = [2,3,5,8,3,5,1,2,6];
arr.sort(@(a,b) a <=> b);
arr.sort(@(a,b) -(a <=> b));
```

that could have been written as:

```
local arr = [2,3,5,8,3,5,1,2,6];
arr.sort(function(a,b) { return a <=> b; } );
arr.sort(function(a,b) { return -(a <=> b); } );
```

other than being limited to a single expression lambdas support all features of regular functions. in fact are implemented as a compile time feature.

2.8.7 Free Variables

A free variable is a variable external from the function scope as is not a local variable or parameter of the function. Free variables reference a local variable from a outer scope. In the following example the variables ‘testy’, ‘x’ and ‘y’ are bound to the function ‘foo’.

```
local x=10,y=20
local testy="I'm testy"

function foo(a,b)
{
  ::print(testy);
  return a+b+x+y;
}
```

A program can read or write a free variable.

2.8.8 Tail Recursion

Tail recursion is a method for partially transforming a recursion in a program into an iteration: it applies when the recursive calls in a function are the last executed statements in that function (just before the return). If this happens the squirrel interpreter collapses the caller stack frame before the recursive call; because of that very deep recursions are possible without risk of a stack overflow.

```
function loopy(n)
{
  if(n>0) {
    ::print("n="+n+"\n");
    return loopy(n-1);
  }
}

loopy(1000);
```

2.9 Classes

Squirrel implements a class mechanism similar to languages like Java/C++/etc... however because of its dynamic nature it differs in several aspects. Classes are first class objects like integer or strings and can be stored in table slots local variables, arrays and passed as function parameters.

2.9.1 Class Declaration

A class object is created through the keyword 'class' . The class object follows the same declaration syntax of a table(see [Tables](#)) with the only difference of using ';' as optional separator rather than ','.

For instance:

```
class Foo {
  //constructor
  constructor(a)
  {
    testy = ["stuff",1,2,3,a];
  }
  //member function
  function PrintTesty()
  {
    foreach(i,val in testy)
    {
      ::print("idx = "+i+" = "+val+" \n");
    }
  }
  //property
  testy = null;
}
```

the previous code example is a syntactic sugar for:

```
Foo <- class {
  //constructor
  constructor(a)
  {
    testy = ["stuff",1,2,3,a];
  }
  //member function
  function PrintTesty()
  {
    foreach(i,val in testy)
    {
      ::print("idx = "+i+" = "+val+" \n");
    }
  }
  //property
  testy = null;
}
```

in order to emulate namespaces, it is also possible to declare something like this:

```

//just 2 regular nested tables
FakeNamespace <- {
  Utils = {}
}

class FakeNamespace.Utils.SuperClass {
  constructor()
  {
    ::print("FakeNamespace.Utils.SuperClass")
  }
  function DoSomething()
  {
    ::print("DoSomething()")
  }
}

function FakeNamespace::Utils::SuperClass::DoSomethingElse()
{
  ::print("FakeNamespace::Utils::SuperClass::DoSomethingElse()")
}

local testy = FakeNamespace.Utils.SuperClass();
testy.DoSomething();
testy.DoSomethingElse();

```

After its declaration, methods or properties can be added or modified by following the same rules that apply to a table(operator <-):.

```

//adds a new property
Foo.stuff <- 10;

//modifies the default value of an existing property
Foo.testy <- "I'm a string";

//adds a new method
function Foo::DoSomething(a,b)
{
  return a+b;
}

```

After a class is instantiated is no longer possible to add new properties however is possible to add or replace methods.

Static variables

Squirrel's classes support static member variables. A static variable shares its value between all instances of the class. Statics are declared by prefixing the variable declaration with the keyword `static`; the declaration must be in the class body.

Note: Statics are read-only.

```

class Foo {
  constructor()
  {
    //..stuff
  }
}

```

(continues on next page)

(continued from previous page)

```

}
name = "normal variable";
//static variable
static classname = "The class name is foo";
};

```

Class Attributes

Classes allow to associate attributes to it's members. Attributes are a form of metadata that can be used to store application specific informations, like documentations strings, properties for IDEs, code generators etc... Class attributes are declared in the class body by preceding the member declaration and are delimited by the symbol `</` and `/>`. Here an example:

```

class Foo </ test = "I'm a class level attribute" />{
  </ test = "freakin attribute" /> //attributes of PrintTesty
  function PrintTesty()
  {
    foreach(i,val in testy)
    {
      ::print("idx = "+i+" = "+val+" \n");
    }
  }
  </ flippy = 10 , second = [1,2,3] /> //attributes of testy
  testy = null;
}

```

Attributes are, matter of fact, a table. Squirrel uses `</ />` syntax instead of curly brackets `{ }` for the attribute declaration to increase readability.

This means that all rules that apply to tables apply to attributes.

Attributes can be retrieved through the built-in function `classobj.getattributes(membername)` (see [built-in functions](#)). and can be modified/added through the built-in function `classobj.setattributes(membername, val)`.

the following code iterates through the attributes of all Foo members.:

```

foreach(member, val in Foo)
{
  ::print(member+"\n");
  local attr;
  if((attr = Foo.getattributes(member)) != null) {
    foreach(i,v in attr)
    {
      ::print("\t"+i+" = "+(typeof v)+"\n");
    }
  }
  else {
    ::print("\t<no attributes>\n")
  }
}

```

2.9.2 Class Instances

The class objects inherits several of the table's feature with the difference that multiple instances of the same class can be created. A class instance is an object that share the same structure of the table that created it but holds its own values. Class *instantiation* uses function notation. A class instance is created by calling a class object. Can be useful to imagine a class like a function that returns a class instance.:

```
//creates a new instance of Foo
local inst = Foo();
```

When a class instance is created its member are initialized *with the same value* specified in the class declaration. The values are copied verbatim, *no cloning is performed* even if the value is a container or a class instances.

Note: FOR C# and Java programmers:

Squirrel doesn't clone member's default values nor executes the member declaration for each instance(as C# or java).

So consider this example:

```
class Foo {
  myarray = [1,2,3]
  mytable = {}
}

local a = Foo();
local b = Foo();
```

In the snippet above both instances will refer to the same array and same table.To achieve what a C# or Java programmer would expect, the following approach should be taken.

```
class Foo {
  myarray = null
  mytable = null
  constructor()
  {
    myarray = [1,2,3]
    mytable = {}
  }
}

local a = Foo();
local b = Foo();
```

When a class defines a method called 'constructor', the class instantiation operation will automatically invoke it for the newly created instance. The constructor method can have parameters, this will impact on the number of parameters that the *instantiation operation* will require. Constructors, as normal functions, can have variable number of parameters (using the parameter ...):

```
class Rect {
  constructor(w,h)
  {
    width = w;
    height = h;
  }
  x = 0;
  y = 0;
```

(continues on next page)

(continued from previous page)

```

width = null;
height = null;
}

//Rect's constructor has 2 parameters so the class has to be 'called'
//with 2 parameters
local rc = Rect(100,100);

```

After an instance is created, its properties can be set or fetched following the same rules that apply to tables. Methods cannot be set.

Instance members cannot be removed.

The class object that created a certain instance can be retrieved through the built-in function `instance.getclass()` (see *built-in functions*)

The operator `instanceof` tests if a class instance is an instance of a certain class.:

```

local rc = Rect(100,100);
if(rc instanceof ::Rect) {
    ::print("It's a rect");
}
else {
    ::print("It isn't a rect");
}

```

Note: Since Squirrel 3.x `instanceof` doesn't throw an exception if the left expression is not a class, it simply fails

2.9.3 Inheritance

Squirrel's classes support single inheritance by adding the keyword `extends`, followed by an expression, in the class declaration. The syntax for a derived class is the following:

```

class SuperFoo extends Foo {
    function DoSomething() {
        ::print("I'm doing something");
    }
}

```

When a derived class is declared, Squirrel first copies all base's members in the new class then proceeds with evaluating the rest of the declaration.

A derived class inherit all members and properties of it's base, if the derived class overrides a base function the base implementation is shadowed. It's possible to access a overridden method of the base class by fetching the method from through the 'base' keyword.

Here an example:

```

class Foo {
    function DoSomething() {
        ::print("I'm the base");
    }
};

```

(continues on next page)

(continued from previous page)

```

class SuperFoo extends Foo {
  //overridden method
  function DoSomething() {
    //calls the base method
    base.DoSomething();
    ::print("I'm doing something");
  }
}

```

Same rule apply to the constructor. The constructor is a regular function (apart from being automatically invoked on construction):

```

class BaseClass {
  constructor()
  {
    ::print("Base constructor\n");
  }
}

class ChildClass extends BaseClass {
  constructor()
  {
    base.constructor();
    ::print("Child constructor\n");
  }
}

local test = ChildClass();

```

The base class of a derived class can be retrieved through the built-in method `getbase()`:

```
local thebaseclass = SuperFoo.getbase();
```

Note that because methods do not have special protection policies when calling methods of the same objects, a method of a base class that calls a method of the same class can end up calling an overridden method of the derived class.

A method of a base class can be explicitly invoked by a method of a derived class though the keyword `base` (as in `base.MyMethod()`):

```

class Foo {
  function DoSomething() {
    ::print("I'm the base");
  }
  function DoIt()
  {
    DoSomething();
  }
};

class SuperFoo extends Foo {
  //overridden method
  function DoSomething() {
    ::print("I'm the derived");
  }
  function DoIt() {
    base.DoIt();
  }
}

```

(continues on next page)

```

    }
}

//creates a new instance of SuperFoo
local inst = SuperFoo();

//prints "I'm the derived"
inst.DoIt();

```

2.9.4 Metamethods

Class instances allow the customization of certain aspects of their semantics through metamethods (see *Metamethods*). For C++ programmers: “metamethods behave roughly like overloaded operators”. The metamethods supported by classes are `_add`, `_sub`, `_mul`, `_div`, `_unm`, `_modulo`, `_set`, `_get`, `_typeof`, `_nexti`, `_cmp`, `_call`, `_delslot`, `_tostring`

Class objects instead support only 2 metamethods: `_newmember` and `_inherited`

the following example show how to create a class that implements the metamethod `_add`:

```

class Vector3 {
    constructor(...)
    {
        if (vargv.len() >= 3) {
            x = vargv[0];
            y = vargv[1];
            z = vargv[2];
        }
    }
    function _add(other)
    {
        return ::Vector3(x+other.x,y+other.y,z+other.z);
    }

    x = 0;
    y = 0;
    z = 0;
}

local v0 = Vector3(1,2,3)
local v1 = Vector3(11,12,13)
local v2 = v0 + v1;
::print (v2.x+" "+v2.y+" "+v2.z+"\n");

```

Since version 2.1, classes support 2 metamethods `_inherited` and `_newmember`. `_inherited` is invoked when a class inherits from the one that implements `_inherited`. `_newmember` is invoked for each member that is added to the class (at declaration time).

2.10 Generators

A function that contains a `yield` statement is called ‘generator function’. When a generator function is called, it does not execute the function body, instead it returns a new suspended generator. The returned generator can be resumed through the `resume` statement while it is alive. The `yield` keyword, suspends the execution of a generator and

optionally returns the result of an expression to the function that resumed the generator. The generator dies when it returns, this can happen through an explicit return statement or by exiting the function body; If an unhandled exception (or runtime error) occurs while a generator is running, the generator will automatically die. A dead generator cannot be resumed anymore.:

```
function geny(n)
{
    for (local i=1;i<=n;i+=1)
        yield i;
    return null;
}

local gtor=geny(10);
local x;
while (x=resume gtor) print (x+"\n");
```

the output of this program will be:

```
1
2
3
4
5
6
7
8
9
10
```

generators can also be iterated using the `foreach` statement. When a generator is evaluated by `foreach`, the generator will be resumed for each iteration until it returns. The value returned by the `return` statement will be ignored.

Note: A suspended generator will hold a strong reference to all the values stored in its local variables except the `this` object that is only a weak reference. A running generator hold a strong reference also to the `this` object.

2.11 Constants & Enumerations

Squirrel allows to bind constant values to an identifier that will be evaluated compile-time. This is achieved through constants and Enumerations.

2.11.1 Constants

Constants bind a specific value to an identifier. Constants are similar to global values, except that they are evaluated compile time and their value cannot be changed.

constants values can only be integers, floats or string literals. No expression are allowed. are declared with the following syntax.:

```
const foobar = 100;
const floatbar = 1.2;
const stringbar = "I'm a constant string";
```

constants are always globally scoped, from the moment they are declared, any following code can reference them. Constants will shadow any global slot with the same name(the global slot will remain visible by using the `::` syntax):

```
local x = foobar * 2;
```

2.11.2 Enumerations

As Constants, Enumerations bind a specific value to a name. Enumerations are also evaluated at compile time and their value cannot be changed.

An enum declaration introduces a new enumeration into the program. Enumeration values can only be integers, floats or string literals. No expression are allowed.:

```
enum Stuff {
  first, //this will be 0
  second, //this will be 1
  third //this will be 2
}
```

or:

```
enum Stuff {
  first = 10
  second = "string"
  third = 1.2
}
```

An enum value is accessed in a manner that's similar to accessing a static class member. The name of the member must be qualified with the name of the enumeration, for example `Stuff.second` Enumerations will shadow any global slot with the same name(the global slot will remain visible by using the `::` syntax):

```
local x = Stuff.first * 2;
```

2.11.3 Implementation notes

Enumerations and Constants are a compile-time feature. Only integers, string and floats can be declared as `const/enum`; No expressions are allowed(because they would have to be evaluated compile time). When a `const` or an `enum` is declared, it is added compile time to the `consttable`. This table is stored in the VM shared state and is shared by the VM and all its threads. The `consttable` is a regular squirrel table; In the same way as the `roottable` it can be modified runtime. You can access the `consttable` through the built-in function `getconsttable()` and also change it through the built-in function `setconsttable()`

here some example:

```
//creates a constant
getconsttable()["something"] <- 10"
//creates an enumeration
getconsttable()["somethingelse"] <- { a = "10", c = "20", d = "200"};
//deletes the constant
delete getconsttable()["something"]
//deletes the enumeration
delete getconsttable()["somethingelse"]
```

This system allows to procedurally declare constants and enumerations, it is also possible to assign any squirrel type to a constant/enumeration(function,classes etc...). However this will make serialization of a code chunk impossible.

2.12 Threads

Squirrel supports cooperative threads(also known as coroutines). A cooperative thread is a subroutine that can suspended in mid-execution and provide a value to the caller without returning program flow, then its execution can be resumed later from the same point where it was suspended. At first look a Squirrel thread can be confused with a generator, in fact their behaviour is quite similar. However while a generator runs in the caller stack and can suspend only the local routine stack a thread has its own execution stack, global table and error handler; This allows a thread to suspend nested calls and have it's own error policies.

2.12.1 Using threads

Threads are created through the built-in function 'newthread(func)'; this function gets as parameter a squirrel function and bind it to the new thread objects (will be the thread body). The returned thread object is initially in 'idle' state. the thread can be started with the function 'threadobj.call()'; the parameters passed to 'call' are passed to the thread function.

A thread can be be suspended calling the function suspend(), when this happens the function that wakeup(or started) the thread returns (If a parameter is passed to suspend() it will be the return value of the wakeup function , if no parameter is passed the return value will be null). A suspended thread can be resumed calling the function 'threadobj.wakeup', when this happens the function that suspended the thread will return(if a parameter is passed to wakeup it will be the return value of the suspend function, if no parameter is passed the return value will be null).

A thread terminates when its main function returns or when an unhandled exception occurs during its execution.:

```
function coroutine_test(a,b)
{
  ::print(a+" "+b+"\n");
  local ret = ::suspend("suspend 1");
  ::print("the coroutine says "+ret+"\n");
  ret = ::suspend("suspend 2");
  ::print("the coroutine says "+ret+"\n");
  ret = ::suspend("suspend 3");
  ::print("the coroutine says "+ret+"\n");
  return "I'm done"
}

local coro = ::newthread(coroutine_test);

local susparam = coro.call("test", "coroutine"); //starts the coroutine

local i = 1;
do
{
  ::print("suspend passed ("+susparam+")\n")
  susparam = coro.wakeup("ciao "+i);
  ++i;
}while(coro.getstatus()=="suspended")

::print("return passed ("+susparam+)\n")
```

the result of this program will be:

```
test coroutine
suspend passed (suspend 1)
the coroutine says ciao 1
```

(continues on next page)

(continued from previous page)

```
suspend passed (suspend 2)
the coroutine says ciao 2
suspend passed (suspend 3)
the coroutine says ciao 3
return passed (I'm done).
```

the following is an interesting example of how threads and tail recursion can be combined.:

```
function state1()
{
  ::suspend("state1");
  return state2(); //tail call
}

function state2()
{
  ::suspend("state2");
  return state3(); //tail call
}

function state3()
{
  ::suspend("state3");
  return state1(); //tail call
}

local statethread = ::newthread(state1)

::print(statethread.call()+"\n");

for(local i = 0; i < 10000; i++)
  ::print(statethread.wakeup()+"\n");
```

2.13 Weak References

The weak references allows the programmers to create references to objects without influencing the lifetime of the object itself. In squirrel Weak references are first-class objects created through the built-in method `obj.weakref()`. All types except null implement the `weakref()` method; however in bools, integers, and floats the method simply returns the object itself (this because this types are always passed by value). When a weak references is assigned to a container (table slot, array, class or instance) is treated differently than other objects; When a container slot that hold a weak reference is fetched, it always returns the value pointed by the weak reference instead of the weak reference object. This allow the programmer to ignore the fact that the value handled is weak. When the object pointed by weak reference is destroyed, the weak reference is automatically set to null.:

```
local t = {}
local a = ["first", "second", "third"]
//creates a weakref to the array and assigns it to a table slot
t.thearray <- a.weakref();
```

The table slot ‘`thearray`’ contains a weak reference to an array. The following line prints “first”, because tables (and all other containers) always return the object pointed by a weak ref:

```
print(t.thearray[0]);
```

the only strong reference to the array is owned by the local variable 'a', so because the following line assigns a integer to 'a' the array is destroyed.:

```
a = 123;
```

When an object pointed by a weak ref is destroyed the weak ref is automatically set to null, so the following line will print "null".:

```
::print (typeof (t.thearray))
```

2.13.1 Handling weak references explicitly

If a weak reference is assigned to a local variable, then is treated as any other value.:

```
local t = {}
local weakobj = t.weakref();
```

the following line prints "weakref".:

```
::print (typeof (weakobj))
```

the object pointed by the weakref can be obtained through the built-in method `weakref.ref()`.

The following line prints "table".:

```
::print (typeof (weakobj.ref ()))
```

2.14 Delegation

Squirrel supports implicit delegation. Every table or userdata can have a parent table (delegate). A parent table is a normal table that allows the definition of special behaviors for his child. When a table (or userdata) is indexed with a key that doesn't correspond to one of its slots, the interpreter automatically delegates the get (or set) operation to its parent.:

```
Entity <- {
}

function Entity::DoStuff()
{
    ::print(_name);
}

local newentity = {
    _name="I'm the new entity"
}
newentity.setdelegate(Entity)

newentity.DoStuff(); //prints "I'm the new entity"
```

The delegate of a table can be retrieved through built-in method `table.getdelegate()` .:

```
local thedelegate = newentity.getdelegate();
```

2.15 Metamethods

Metamethods are a mechanism that allows the customization of certain aspects of the language semantics. Those methods are normal functions placed in a table parent(delegate) or class declaration; It is possible to change many aspects of a table/class instance behavior by just defining a metamethod. Class objects (not instances) support only 2 metamethods `_newmember`, `_inherited`.

For example when we use relational operators other than `'=='` on 2 tables, the VM will check if the table has a method in his parent called `'_cmp'`; if so it will call it to determine the relation between the tables.:

```
local comparable={
  _cmp = function (other)
  {
    if(name<other.name) return -1;
    if(name>other.name) return 1;
    return 0;
  }
}

local a={ name="Alberto" }.setdelegate(comparable);
local b={ name="Wouter" }.setdelegate(comparable);

if(a>b)
  print("a>b")
else
  print("b<=a");
```

for classes the previous code become:

```
class Comparable {
  constructor(n)
  {
    name = n;
  }
  function _cmp(other)
  {
    if(name<other.name) return -1;
    if(name>other.name) return 1;
    return 0;
  }
  name = null;
}

local a = Comparable("Alberto");
local b = Comparable("Wouter");

if(a>b)
  print("a>b")
else
  print("b<=a");
```

2.15.1 `_set`

```
_set (idx, val)
```

invoked when the index `idx` is not present in the object or in its delegate chain. `_set` must ‘throw null’ to notify that a key wasn’t found but there were not runtime errors (clean failure). This allows the program to differentiate between a runtime error and a ‘index not found’.

2.15.2 `_get`

```
_get (idx)
```

invoked when the index `idx` is not present in the object or in its delegate chain. `_get` must ‘throw null’ to notify that a key wasn’t found but there were not runtime errors (clean failure). This allows the program to differentiate between a runtime error and a ‘index not found’.

2.15.3 `_newslot`

```
_newslot (key, value)
```

invoked when a script tries to add a new slot in a table.

if the slot already exists in the target table the method will not be invoked also if the “new slot” operator is used.

2.15.4 `_delslot`

```
_delslot (key)
```

invoked when a script deletes a slot from a table. if the method is invoked squirrel will not try to delete the slot himself

2.15.5 `_add`

```
_add (other)
```

the `+` operator

returns `this + other`

2.15.6 `_sub`

```
_sub (other)
```

the `-` operator (like `_add`)

2.15.7 `_mul`

```
_mul (other)
```

the `*` operator (like `_add`)

2.15.8 `_div`

```
_div(other)
```

the `/` operator (like `_add`)

2.15.9 `_modulo`

```
_modulo(other)
```

the `%` operator (like `_add`)

2.15.10 `_unm`

```
_unm()
```

the unary minus operator

2.15.11 `_typeof`

```
_typeof()
```

invoked by the `typeof` operator on tables, userdata, and class instances.

Returns the type of `this` as string

2.15.12 `_cmp`

```
_cmp(other)
```

invoked to emulate the `<` `>` `<=` `>=` and `<=>` operators

returns an integer as follow:

returns	relationship
<code>> 0</code>	if <code>this > other</code>
<code>0</code>	if <code>this == other</code>
<code>< 0</code>	if <code>this < other</code>

2.15.13 `_call`

```
_call(other)
```

invoked when a table, userdata, or class instance is called

2.15.14 `_cloned`

```
_cloned(original)
```

invoked when a table or class instance is cloned(in the cloned table)

2.15.15 `_nexti`

```
_nexti(previdx)
```

invoked when a userdata or class instance is iterated by a foreach loop.

If `previdx==null` it means that it is the first iteration. The function has to return the index of the 'next' value.

2.15.16 `_tostring`

```
_tostring()
```

Invoked when during string concatenation or when the `print` function prints a table, instance, or userdata. The method is also invoked by the `sq_tostring()` API.

Must return a string representation of the object.

2.15.17 `_inherited`

```
_inherited(attributes)
```

invoked when a class object inherits from the class implementing `_inherited`. The `this` contains the new class.

Return value is ignored.

2.15.18 `_newmember`

```
_newmember(index,value,attributes,isstatic)
```

invoked for each member declared in a class body (at declaration time).

If the function is implemented, members will not be added to the class.

2.16 Built-in Functions

2.16.1 Global Symbols

array (*size* [, *fill*])

creates and returns array of a specified size. If the optional parameter `fill` is specified its value will be used to fill the new array's slots. If the `fill` parameter is omitted, `null` is used instead.

seterrorhandler (*func*)

sets the runtime error handler

callee ()

returns the currently running closure

setdebughook (*hook_func*)

sets the debug hook

enabledebuginfo (*enable*)

enable/disable the debug line information generation at compile time. *enable* != null enables. *enable* == null disables.

getroottable ()

returns the root table of the VM.

setroottable (*table*)

sets the root table of the VM. And returns the previous root table.

getconsttable ()

returns the const table of the VM.

setconsttable (*table*)

sets the const table of the VM; returns the previous const table.

assert (*exp* [, *message*])

throws an exception if *exp* is null or false. Throws "assertion failed" string by default, or *message* if specified.

print (*x*)

prints *x* to the standard output

error (*x*)

prints *x* in the standard error output

compilestring (*string* [, *buffername*])

compiles a string containing a squirrel script into a function and returns it:

```
local compiledscript=compilestring("::print(\"ciao\")");
//run the script
compiledscript();
```

collectgarbage ()

Runs the garbage collector and returns the number of reference cycles found (and deleted). This function only works on garbage collector builds.

resurrectunreachable ()

Runs the garbage collector and returns an array containing all unreachable object found. If no unreachable object is found, null is returned instead. This function is meant to help debugging reference cycles. This function only works on garbage collector builds.

type (*obj*)

return the 'raw' type of an object without invoking the metamethod '_typeof'.

getstackinfos (*level*)

returns the stack informations of a given call stack level. returns a table formatted as follow:

```

{
    func="DoStuff", //function name

    src="test.nut", //source file

    line=10,        //line number

    locals = {      //a table containing the local variables
        a=10,

        testy="I'm a string"
    }
}

```

level = 0 is `getstackinfos()` itself! level = 1 is the current function, level = 2 is the caller of the current function, and so on. If the stack level doesn't exist the function returns null.

newthread (*threadfunc*)

creates a new cooperative thread object(coroutine) and returns it

__versionnumber__

integer values describing the version of VM and compiler. e.g. for Squirrel 3.0.1 this value will be 301

__version__

string values describing the version of VM and compiler.

__charsize__

size in bytes of the internal VM representation for characters(1 for ASCII builds 2 for UNICODE builds).

__intsize__

size in bytes of the internal VM representation for integers(4 for 32bits builds 8 for 64bits builds).

__floatsize__

size in bytes of the internal VM representation for floats(4 for single precision builds 8 for double precision builds).

Default delegates

Except null and userdata every squirrel object has a default delegate containing a set of functions to manipulate and retrieve information from the object itself.

2.16.2 Integer

`integer.tofloat()`

convert the number to float and returns it

`integer.tostring()`

converts the number to string and returns it

`integer.tointeger()`

dummy function; returns the value of the integer.

`integer.tochar()`

returns a string containing a single character represented by the integer.

`integer.weakref()`

dummy function; returns the integer itself.

2.16.3 Float

`float.tofloat()`

returns the value of the float(dummy function)

`float.tointeger()`

converts the number to integer and returns it

`float.tostring()`

converts the number to string and returns it

`float.tochar()`

returns a string containing a single character represented by the integer part of the float.

`float.weakref()`

dummy function; returns the float itself.

2.16.4 Bool

`bool.tofloat()`

returns 1.0 for true 0.0 for false

`bool.tointeger()`

returns 1 for true 0 for false

`bool.tostring()`

returns “true” for true and “false” for false

`bool.weakref()`

dummy function; returns the bool itself.

2.16.5 String

`string.len()`

returns the string length

`string.tointeger([base])`

Converts the string to integer and returns it. An optional parameter base can be specified—if a base is not specified, it defaults to base 10.

`string.tofloat()`

converts the string to float and returns it

`string.tostring()`

returns the string (really, a dummy function)

`string.slice(start[, end])`

returns a section of the string as new string. Copies from start to the end (not included). If start is negative the index is calculated as length + start, if end is negative the index is calculated as length + end. If end is omitted end is equal to the string length.

`string.find(substr[, startidx])`

Searches a sub string (substr) starting from the index startidx and returns the index of its first occurrence. If startidx is omitted the search operation starts from the beginning of the string. The function returns null if substr is not found.

`string.tolower()`

returns a lowercase copy of the string.

`string.toupper()`

returns an uppercase copy of the string.

`string.weakref()`

returns a weak reference to the object.

2.16.6 Table

`table.len()`

returns the number of slots contained in a table

`table.rawget(key)`

tries to get a value from the slot 'key' without employing delegation

`table.rawset(key, val)`

Sets the slot 'key' with the value 'val' without employing delegation. If the slot does not exist, it will be created. Returns table itself.

`table.rawdelete()`

Deletes the slot key without employing delegation and returns its value. If the slot does not exist, returns null.

`table.rawin(key)`

returns true if the slot 'key' exists. the function has the same effect as the operator 'in' but does not employ delegation.

`table.weakref()`

returns a weak reference to the object.

`table.tostring()`

Tries to invoke the `_tostring` metaclass. If that fails, it returns "(table : pointer)".

`table.clear()`

removes all the slots from the table. Returns table itself.

`table.setdelegate(table)`

Sets the delegate of the table. To remove a delegate, 'null' must be passed to the function. The function returns the table itself (e.g. `a.setdelegate(b)` – in this case 'a' is the return value).

`table.getdelegate()`

returns the table's delegate or null if no delegate was set.

`table.filter (func(key, val))`

Creates a new table with all values that pass the test implemented by the provided function. In detail, it creates a new table, invokes the specified function for each key-value pair in the original table; if the function returns 'true', then the value is added to the newly created table at the same key.

`table.keys ()`

returns an array containing all the keys of the table slots.

`table.values ()`

returns an array containing all the values of the table slots.

2.16.7 Array

`array.len ()`

returns the length of the array

`array.append (val)`

appends the value 'val' at the end of the array. Returns array itself.

`array.push (val)`

appends the value 'val' at the end of the array. Returns array itself.

`array.extend (array)`

Extends the array by appending all the items in the given array. Returns array itself.

`array.pop ()`

removes a value from the back of the array and returns it.

`array.top ()`

returns the value of the array with the higher index

`array.insert (idx, val)`

inserts the value 'val' at the position 'idx' in the array. Returns array itself.

`array.remove (idx)`

removes the value at the position 'idx' in the array and returns its value.

`array.resize (size[, fill])`

Resizes the array. If the optional parameter 'fill' is specified, its value will be used to fill the new array's slots when the size specified is bigger than the previous size. If the fill parameter is omitted, null is used instead. Returns array itself.

`array.sort ([compare_func])`

Sorts the array in-place. A custom compare function can be optionally passed. The function prototype as to be the following.:

```
function custom_compare(a,b)
{
  if(a>b) return 1
  else if(a<b) return -1
  return 0;
}
```

a more compact version of a custom compare can be written using a lambda expression and the operator `<=>`

```
arr.sort(@(a,b) a <=> b);
```

Returns array itself.

`array.reverse()`

reverse the elements of the array in place. Returns array itself.

`array.slice(start[, end])`

Returns a section of the array as new array. Copies from start to the end (not included). If start is negative the index is calculated as length + start, if end is negative the index is calculated as length + end. If end is omitted end is equal to the array length.

`array.weakref()`

returns a weak reference to the object.

`array.toString()`

returns the string "(array : pointer)".

`array.clear()`

removes all the items from the array

`array.map(func(item_value, [item_index], [array_ref]))`

Creates a new array of the same size. For each element in the original array invokes the function 'func' and assigns the return value of the function to the corresponding element of the newly created array. Provided func can accept up to 3 arguments: array item value (required), array item index (optional), reference to array itself (optional).

`array.apply(func([item_value, [item_index], [array_ref]))`

for each element in the array invokes the function 'func' and replace the original value of the element with the return value of the function.

`array.reduce(func(prevval, curval)[, initializer])`

Reduces an array to a single value. For each element in the array invokes the function 'func' passing the initial value (or value from the previous callback call) and the value of the current element. The return value of the function is then used as 'prevval' for the next element. If the optional initializer is present, it is placed before the items of the array in the calculation, and serves as a default when the sequence is empty. If initializer is not given then for sequence contains only one item, reduce() returns the first item, and for empty sequence returns null.

Given an sequence with 2 or more elements (including initializer) calls the function with the first two elements as the parameters, gets that result, then calls the function with that result and the third element, gets that result, calls the function with that result and the fourth parameter and so on until all element have been processed. Finally, returns the return value of the last invocation of func.

`array.filter(func(index, val))`

Creates a new array with all elements that pass the test implemented by the provided function. In detail, it creates a new array, for each element in the original array invokes the specified function passing the index of the element and it's value; if the function returns 'true', then the value of the corresponding element is added on the newly created array.

`array.find(value)`

Performs a linear search for the value in the array. Returns the index of the value if it was found null otherwise.

2.16.8 Function

`function.call` (*_this*, *args...*)

calls the function with the specified environment object('this') and parameters

`function.pcall` (*_this*, *args...*)

calls the function with the specified environment object('this') and parameters, this function will not invoke the error callback in case of failure(pcall stays for 'protected call')

`function.acall` (*array_args*)

calls the function with the specified environment object('this') and parameters. The function accepts an array containing the parameters that will be passed to the called function. Where *array_args* has to contain the required 'this' object at the [0] position.

`function.pacall` (*array_args*)

calls the function with the specified environment object('this') and parameters. The function accepts an array containing the parameters that will be passed to the called function. Where *array_args* has to contain the required 'this' object at the [0] position. This function will not invoke the error callback in case of failure(pacall stays for 'protected array call')

`function.weakref` ()

returns a weak reference to the object.

`function.tostring` ()

returns the string "(closure : pointer)".

`function.setroot` (*table*)

sets the root table of a closure

`function.getroot` ()

returns the root table of the closure

`function.bindenv` (*env*)

clones the function(aka closure) and bind the environment object to it(table,class or instance). the this parameter of the newly create function will always be set to env. Note that the created function holds a weak reference to its environment object so cannot be used to control its lifetime.

`function.getinfos` ()

returns a table containing informations about the function, like parameters, name and source name;

```
//the data is returned as a table is in form
//pure squirrel function
{
  native = false
  name = "zefuncname"
  src = "/something/something.nut"
  parameters = ["a", "b", "c"]
  defparams = [1, "def"]
  varargs = 2
}
//native C function
{
  native = true
  name = "zefuncname"
```

(continues on next page)

(continued from previous page)

```

paramscheck = 2
typecheck = [83886082, 83886384] //this is the typemask (see C defines OT_INTEGER, OT_
↪FLOAT etc...)
}

```

2.16.9 Class

`class.instance()`

returns a new instance of the class. this function does not invoke the instance constructor. The constructor must be explicitly called (eg. `class_inst.constructor(class_inst)`).

`class.getattributes(membername)`

returns the attributes of the specified member. if the parameter member is null the function returns the class level attributes.

`class.setattributes(membername, attr)`

sets the attribute of the specified member and returns the previous attribute value. if the parameter member is null the function sets the class level attributes.

`class.rawin(key)`

returns true if the slot 'key' exists. the function has the same effect as the operator 'in' but does not employ delegation.

`class.weakref()`

returns a weak reference to the object.

`class.tostring()`

returns the string "(class : pointer)".

`class.rawget(key)`

tries to get a value from the slot 'key' without employing delegation

`class.rawset(key, val)`

sets the slot 'key' with the value 'val' without employing delegation. If the slot does not exist, it will be created.

`class.newmember(key, val[, attrs][, bstatic])`

sets/adds the slot 'key' with the value 'val' and attributes 'attrs' and if present invokes the `_newmember` metaclass. If `bstatic` is true the slot will be added as static. If the slot does not exist, it will be created.

`class.rawnewmember(key, val[, attrs][, bstatic])`

sets/adds the slot 'key' with the value 'val' and attributes 'attrs'. If `bstatic` is true the slot will be added as static. If the slot does not exist, it will be created. It doesn't invoke any metaclass.

2.16.10 Class Instance

`instance.getclass()`

returns the class that created the instance.

`instance.rawin(key)`

Arguments

- **key** – ze key

returns true if the slot 'key' exists. the function has the same effect as the operator 'in' but does not employ delegation.

`instance.weakref()`

returns a weak reference to the object.

`instance.tostring()`

tries to invoke the `_tostring` metamethod, if failed. returns "(instance : pointer)".

`instance.rawget(key)`

tries to get a value from the slot 'key' without employing delegation

`instance.rawset(key, val)`

sets the slot 'key' with the value 'val' without employing delegation. If the slot does not exists, it will be created.

2.16.11 Generator

`generator.getstatus()`

returns the status of the generator as string : "running", "dead" or "suspended".

`generator.weakref()`

returns a weak reference to the object.

`generator.tostring()`

returns the string "(generator : pointer)".

2.16.12 Thread

`thread.call(...)`

starts the thread with the specified parameters

`thread.wakeup([wakeupval])`

wakes up a suspended thread, accepts a optional parameter that will be used as return value for the function that suspended the thread(usually `suspend()`)

`thread.wakeupthrow(objtothrow[, propagateerror = true])`

wakes up a suspended thread, throwing an exception in the awoken thread, throwing the object 'objtothrow'.

`thread.getstatus()`

returns the status of the thread ("idle","running","suspended")

`thread.weakref()`

returns a weak reference to the object.

`thread.tostring()`

returns the string "(thread : pointer)".

`thread.getstackinfos(stacklevel)`

returns the stack frame informations at the given stack level (0 is the current function 1 is the caller and so on).

2.16.13 Weak Reference

`weakreference.ref()`

returns the object that the weak reference is pointing at; null if the object that was point at was destroyed.

`weakreference.weakref()`

returns a weak reference to the object.

`weakreference.tostring()`

returns the string “(weakref : pointer)”.

EMBEDDING SQUIRREL

This section describes how to embed Squirrel in a host application, C language knowledge is required to understand this part of the manual.

Because of his nature of extension language, Squirrel's compiler and virtual machine are implemented as C library. The library exposes a set of functions to compile scripts, call functions, manipulate data and extend the virtual machine. All declarations needed for embedding the language in an application are in the header file 'squirrel.h'.

3.1 Memory Management

Squirrel uses reference counting (RC) as primary system for memory management; however, the virtual machine (VM) has an auxiliary mark and sweep garbage collector that can be invoked on demand.

There are 2 possible compile time options:

- The default configuration consists in RC plus a mark and sweep garbage collector. The host program can call the function `sq_collectgarbage()` and perform a garbage collection cycle during the program execution. The garbage collector isn't invoked by the VM and has to be explicitly called by the host program.
- The second a situation consists in RC only(define `NO_GARBAGE_COLLECTOR`); in this case is impossible for the VM to detect reference cycles, so is the programmer that has to solve them explicitly in order to avoid memory leaks.

The only advantage introduced by the second option is that saves 2 additional pointers that have to be stored for each object in the default configuration with garbage collector(8 bytes for 32 bits systems). The types involved are: tables, arrays, functions, threads, userdata and generators; all other types are untouched. These options do not affect execution speed.

3.2 Build Configuration

3.2.1 Unicode

By default Squirrel strings are plain 8-bits ASCII characters; however if the symbol 'SQUNICODE' is defined the VM, compiler and API will use 16-bit characters (UCS2).

3.2.2 Squirrel on 64-bit architectures

Squirrel can be compiled on 64-bit architectures by defining '`_SQ64`' in the C++ preprocessor. This flag should be defined in any project that includes 'squirrel.h'.

3.2.3 Userdata Alignment

Both class instances and userdatas can have a buffer associated to them. Squirrel specifies the alignment(in bytes) through the preprocessor defining 'SQ_ALIGNMENT'. By default SQ_ALIGNMENT is defined as 4 for 32-bit builds and 8 for 64-bit builds and builds that use 64-bit floats. It is possible to override the value of SQ_ALIGNMENT respecting the following rules. SQ_ALIGNMENT shall be less than or equal to SQ_MALLOC alignments, and it shall be power of 2.

Note: This only applies for userdata allocated by the VM, specified via `sq_setclassudsize()` or belonging to a userdata object. userpointers specified by the user are not affected by alignment rules.

3.2.4 Stand-alone VM without compiler

Squirrel's VM can be compiled without its compiler by defining 'NO_COMPILER' in the C++ preprocessor. When 'NO_COMPILER' is defined all function related to the compiler (eg. `sq_compile`) will fail. Other functions that conditionally load precompiled bytecode or compile a file (eg. `sqstd_dofile`) will only work with precompiled bytecode.

3.3 Error Conventions

Most of the functions in the API return a SQRESULT value; SQRESULT indicates if a function completed successfully or not. The macros `SQ_SUCCEEDED()` and `SQ_FAILED()` are used to test the result of a function.:

```
if(SQ_FAILED(sq_getstring(v,-1,&s)))
    printf("getstring failed");
```

3.4 Virtual Machine Initialization

The first thing that a host application has to do, is create a virtual machine. The host application can create any number of virtual machines through the function `sq_open()`. Every single VM that was created using `sq_open()` has to be released with the function `sq_close()` when it is no longer needed.:

```
int main(int argc, char* argv[])
{
    HSQUIRRELVm v;
    v = sq_open(1024); //creates a VM with initial stack size 1024

    //do some stuff with squirrel here

    sq_close(v);
}
```

3.5 The Stack

Squirrel exchanges values with the virtual machine through a stack. This mechanism has been inherited from the language Lua. For instance to call a Squirrel function from C it is necessary to push the function and the arguments in the stack and then invoke the function; also when Squirrel calls a C function the parameters will be in the stack as well.

3.5.1 Stack indexes

Many API functions can arbitrarily refer to any element in the stack through an index. The stack indexes follow those conventions:

- 1 is the stack base
- Negative indexes are considered an offset from top of the stack. For instance -1 is the top of the stack.
- 0 is an invalid index

Here an example (let's pretend that this table is the VM stack)

STACK	positive index	negative index
"test"	4	-1(top)
1	3	-2
0.5	2	-3
"foo"	1(base)	-4

In this case, the function `sq_gettop` would return 4;

3.5.2 Stack manipulation

The API offers several functions to push and retrieve data from the Squirrel stack.

To push a value that is already present in the stack in the top position:

```
void sq_push(HSQIRRELVM v, SQInteger idx);
```

To pop an arbitrary number of elements:

```
void sq_pop(HSQIRRELVM v, SQInteger nelemstopop);
```

To remove an element from the stack:

```
void sq_remove(HSQIRRELVM v, SQInteger idx);
```

To retrieve the top index (and size) of the current virtual stack you must call `sq_gettop`

```
SQInteger sq_gettop(HSQIRRELVM v);
```

To force the stack to a certain size you can call `sq_settop`

```
void sq_settop(HSQIRRELVM v, SQInteger newtop);
```

If the newtop is bigger than the previous one, the new positions in the stack will be filled with null values.

The following function pushes a C value into the stack:

```
void sq_pushstring(HSQIRRELVM v, const SQChar *s, SQInteger len);
void sq_pushfloat(HSQIRRELVM v, SQFloat f);
void sq_pushinteger(HSQIRRELVM v, SQInteger n);
void sq_pushuserpointer(HSQIRRELVM v, SQUserPointer p);
void sq_pushbool(HSQIRRELVM v, SQBool b);
```

this function pushes a null into the stack:

```
void sq_pushnull(HSQIRRELVM v);
```

returns the type of the value in a arbitrary position in the stack:

```
SQObjectType sq_gettype(HSQIRRELVM v, SQInteger idx);
```

the result can be one of the following values:

```
OT_NULL, OT_INTEGER, OT_FLOAT, OT_STRING, OT_TABLE, OT_ARRAY, OT_USERDATA,  
OT_CLOSURE, OT_NATIVECLOSURE, OT_GENERATOR, OT_USERPOINTER, OT_BOOL, OT_INSTANCE, OT_CLASS,  
↪ OT_WEAKREF
```

The following functions convert a squirrel value in the stack to a C value:

```
SQRESULT sq_getstring(HSQIRRELVM v, SQInteger idx, const SQChar **c);  
SQRESULT sq_getstringandsize(HSQIRRELVM v, SQInteger idx, const SQChar **c, SQInteger_  
↪ size);  
SQRESULT sq_getinteger(HSQIRRELVM v, SQInteger idx, SQInteger *i);  
SQRESULT sq_getfloat(HSQIRRELVM v, SQInteger idx, SQFloat *f);  
SQRESULT sq_getuserpointer(HSQIRRELVM v, SQInteger idx, SQUserPointer *p);  
SQRESULT sq_getuserdata(HSQIRRELVM v, SQInteger idx, SQUserPointer *p, SQUserPointer_  
↪ *typetag);  
SQRESULT sq_getbool(HSQIRRELVM v, SQInteger idx, SQBool *p);
```

The function `sq_cmp` compares 2 values from the stack and returns their relation (like `strcmp()` in ANSI C):

```
SQInteger sq_cmp(HSQIRRELVM v);
```

3.6 Runtime error handling

When an exception is not handled by Squirrel code with a `try/catch` statement, a runtime error is raised and the execution of the current program is interrupted. It is possible to set a call back function to intercept the runtime error from the host program; this is useful to show meaningful errors to the script writer and for implementing visual debuggers. The following API call pops a Squirrel function from the stack and sets it as error handler:

```
SQUIRREL_API void sq_seterrorhandler(HSQIRRELVM v);
```

The error handler is called with 2 parameters, an environment object (`this`) and a object. The object can be any squirrel type.

3.7 Compiling a script

You can compile a Squirrel script with the function `sq_compile`:

```
typedef SQInteger (*SQLEXREADFUNC)(SQUserPointer userdata);  
  
SQRESULT sq_compile(HSQIRRELVM v, SQLEXREADFUNC read, SQUserPointer p,  
                  const SQChar *sourcename, SQBool raiseerror);
```

In order to compile a script is necessary for the host application to implement a reader function (`SQLEXREADFUNC`); this function is used to feed the compiler with the script data. The function is called every time the compiler needs a character; It has to return a character code if succeed or 0 if the source is finished.

If `sq_compile` succeeds, the compiled script will be pushed as Squirrel function in the stack.

Here an example of a 'read' function that read from a file:

```

SQInteger file_lexfeedASCII(SQUserPointer file)
{
    int ret;
    char c;
    if( ( ret=fread(&c,sizeof(c),1,(FILE *)file )>0) )
        return c;
    return 0;
}

int compile_file(HSQIRRELVM v,const char *filename)
{
    FILE *f=fopen(filename,"rb");
    if(f)
    {
        sq_compile(v,file_lexfeedASCII,f,filename,1);
        fclose(f);
        return 1;
    }
    return 0;
}

```

When the compiler fails for a syntax error it will try to call the 'compiler error handler'; this function must be declared as follow:

```

typedef void (*SQCOMPILERERROR)(HSQIRRELVM /*v*/,const SQChar * /*desc*/,const_
↪SQChar * /*source*/,
                                SQInteger /*line*/,SQInteger /*column*/);

```

and can be set with the following API call:

```

void sq_setcompilererrorhandler(HSQIRRELVM v,SQCOMPILERERROR f);

```

3.8 Calling a function

To call a squirrel function it is necessary to push the function in the stack followed by the parameters and then call the function `sq_call`. The function will pop the parameters and push the return value if the last `sq_call` parameter is `> 0`.

```

sq_pushroottable(v);
sq_pushstring(v,"foo",-1);
sq_get(v,-2); //get the function from the root table
sq_pushroottable(v); // 'this' (function environment object)
sq_pushinteger(v,1);
sq_pushfloat(v,2.0);
sq_pushstring(v,"three",-1);
sq_call(v,4,SQFalse,SQFalse);
sq_pop(v,2); //pops the roottable and the function

```

this is equivalent to the following Squirrel code:

```

foo(1,2.0,"three");

```

If a runtime error occurs (or a exception is thrown) during the squirrel code execution the `sq_call` will fail.

3.9 Create a C function

A native C function must have the following prototype:

```
typedef SQInteger (*SQFUNCTION) (HSQUIRRELVN);
```

The parameters is an handle to the calling VM and the return value is an integer respecting the following rules:

- 1 if the function returns a value
- 0 if the function does not return a value
- SQ_ERROR runtime error is thrown

In order to obtain a new callable squirrel function from a C function pointer, is necessary to call `sq_newclosure()` passing the C function to it; the new Squirrel function will be pushed in the stack.

When the function is called, the stackbase is the first parameter of the function and the top is the last. In order to return a value the function has to push it in the stack and return 1.

Function parameters are in the stack from position 1 ('this') to *n*. `sq_gettop()` can be used to determinate the number of parameters.

If the function has free variables, those will be in the stack after the explicit parameters and can be handled as normal parameters. Note also that the value returned by `sq_gettop()` will be affected by free variables. `sq_gettop()` will return the number of parameters plus number of free variables.

Here an example, the following function print the value of each argument and return the number of arguments.

```
SQInteger print_args(HSQUIRRELVN v)
{
    SQInteger nargs = sq_gettop(v); //number of arguments
    for(SQInteger n=1;n<=nargs;n++)
    {
        printf("arg %d is ",n);
        switch(sq_gettype(v,n))
        {
            case OT_NULL:
                printf("null");
                break;
            case OT_INTEGER:
                printf("integer");
                break;
            case OT_FLOAT:
                printf("float");
                break;
            case OT_STRING:
                printf("string");
                break;
            case OT_TABLE:
                printf("table");
                break;
            case OT_ARRAY:
                printf("array");
                break;
            case OT_USERDATA:
                printf("userdata");
                break;
            case OT_CLOSURE:
                printf("closure(function)");
```

(continues on next page)

(continued from previous page)

```

        break;
    case OT_NATIVECLOSURE:
        printf("native closure(C function)");
        break;
    case OT_GENERATOR:
        printf("generator");
        break;
    case OT_USERPOINTER:
        printf("userpointer");
        break;
    case OT_CLASS:
        printf("class");
        break;
    case OT_INSTANCE:
        printf("instance");
        break;
    case OT_WEAKREF:
        printf("weak reference");
        break;
    default:
        return sq_throwerror(v, "invalid param"); //throws an exception
    }
}
printf("\n");
sq_pushinteger(v, nargs); //push the number of arguments as return value
return 1; //1 because 1 value is returned
}

```

Here an example of how to register a function:

```

SQInteger register_global_func(HSQIRRELVM v, SQFUNCTION f, const char *fname)
{
    sq_pushroottable(v);
    sq_pushstring(v, fname, -1);
    sq_newclosure(v, f, 0); //create a new function
    sq_newslot(v, -3, SQFalse);
    sq_pop(v, 1); //pops the root table
    return 0;
}

```

3.10 Tables and arrays manipulation

A new table is created calling `sq_newtable`, this function pushes a new table in the stack.:

```
void sq_newtable(HSQIRRELVM v);
```

To create a new slot:

```
SQRESULT sq_newslot(HSQIRRELVM v, SQInteger idx, SQBool bstatic);
```

To set or get the table delegate:

```
SQRESULT sq_setdelegate(HSQIRRELVM v, SQInteger idx);
SQRESULT sq_getdelegate(HSQIRRELVM v, SQInteger idx);
```

A new array is created calling `sq_newarray`, the function pushes a new array in the stack; if the parameters size is bigger than 0 the elements are initialized to null.:

```
void sq_newarray (HSQUIRRELV v, SQInteger size);
```

To append a value to the back of the array:

```
SQRESULT sq_arrayappend(HSQUIRRELV v, SQInteger idx);
```

To remove a value from the back of the array:

```
SQRESULT sq_arraypop(HSQUIRRELV v, SQInteger idx, SQInteger pushval);
```

To resize the array:

```
SQRESULT sq_arrayresize(HSQUIRRELV v, SQInteger idx, SQInteger newsize);
```

To retrieve the size of a table or an array you must use `sq_getsize()`:

```
SQInteger sq_getsize(HSQUIRRELV v, SQInteger idx);
```

To set a value in an array or table:

```
SQRESULT sq_set(HSQUIRRELV v, SQInteger idx);
```

To get a value from an array or table:

```
SQRESULT sq_get(HSQUIRRELV v, SQInteger idx);
```

To get or set a value from a table without employing delegation:

```
SQRESULT sq_rawget(HSQUIRRELV v, SQInteger idx);  
SQRESULT sq_rawset(HSQUIRRELV v, SQInteger idx);
```

To iterate a table or an array:

```
SQRESULT sq_next(HSQUIRRELV v, SQInteger idx);
```

Here an example of how to perform an iteration:

```
//push your table/array here  
sq_pushnull(v) //null iterator  
while (SQ_SUCCEEDED(sq_next(v, -2)))  
{  
    //here -1 is the value and -2 is the key  
  
    sq_pop(v, 2); //pops key and val before the nex iteration  
}  
  
sq_pop(v, 1); //pops the null iterator
```

3.11 Userdata and UserPointers

Squirrel allows the host application put arbitrary data chunks into a Squirrel value, this is possible through the data type userdata.:

```
SQUserPointer sq_newuserdata(HSQUIRRELVm v, SQUnsignedInteger size);
```

When the function `sq_newuserdata` is called, Squirrel allocates a new userdata with the specified size, returns a pointer to his payload buffer and push the object in the stack; at this point the application can do whatever it want with this memory chunk, the VM will automatically take care of the memory deallocation like for every other built-in type. A userdata can be passed to a function or stored in a table slot. By default Squirrel cannot manipulate directly userdata; however is possible to assign a delegate to it and define a behavior like it would be a table. Because the application would want to do something with the data stored in a userdata object when it get deleted, is possible to assign a callback that will be called by the VM just before deleting a certain userdata. This is done through the API call `sq_setreleasehook`:

```
typedef SQInteger (*SQRELEASEHOOK) (SQUserPointer, SQInteger size);
void sq_setreleasehook(HSQUIRRELVm v, SQInteger idx, SQRELEASEHOOK hook);
```

Another kind of userdata is the userpointer; this type is not a memory chunk like the normal userdata, but just a 'void*' pointer. It cannot have a delegate and is passed by value, so pushing a userpointer doesn't cause any memory allocation:

```
void sq_pushuserpointer(HSQUIRRELVm v, SQUserPointer p);
```

3.12 The registry table

The registry table is an hidden table shared between vm and all his thread(friend vms). This table is accessible only through the C API and is meant to be an utility structure for native C library implementation. For instance the `sqstdlib`(squirrel standard library)uses it to store configuration and shared objects delegates. The registry is accessible through the API call `sq_pushregistrytable`:

```
void sq_pushregistrytable(HSQUIRRELVm v);
```

3.13 Mantaining references to Squirrel values from the C API

Squirrel allows to reference values through the C API; the function `sq_getstackobj`() gets a handle to a squirrel object(any type). The object handle can be used to control the lifetime of an object by adding or removing references to it(see `sq_addrf`() and `sq_release`()). The object can be also re-pushed in the VM stack using `sq_pushobject`():

```
HSQOBJECT obj;

sq_resetobject(&obj); //initialize the handle
sq_getstackobj(v, -2, &obj); //retrieve an object handle from the pos -2
sq_addrf(v, &obj); //adds a reference to the object

... //do stuff

sq_pushobject(v, obj); //push the object in the stack
sq_release(v, &obj); //relese the object
```

3.14 Debug Interface

The squirrel VM exposes a very simple debug interface that allows to easily built a full featured debugger. Through the functions `sq_setdebughook` and `sq_setnatividebughook` is possible in fact to set a callback function that will be called every time the VM executes an new line of a script or if a function get called/returns. The callback will pass as argument the current line the current source and the current function name (if any):

```
SQUIRREL_API void sq_setdebughook(HSQUIRRELVM v);
```

or

```
SQUIRREL_API void sq_setnatividebughook(HSQUIRRELVM v, SQDEBUGHOOK hook);
```

The following code shows how a debug hook could look like(Obviously is possible to implement this function in C as well).

```
function debughook(event_type, sourcefile, line, funcname)
{
    local fname=funcname?funcname:"unknown";
    local srcfile=sourcefile?sourcefile:"unknown"
    switch (event_type) {
    case 'l': //called every line(that contains some code)
        ::print("LINE line [" + line + "] func [" + fname + "]");
        ::print("file [" + srcfile + "]\n");
        break;
    case 'c': //called when a function has been called
        ::print("LINE line [" + line + "] func [" + fname + "]");
        ::print("file [" + srcfile + "]\n");
        break;
    case 'r': //called when a function returns
        ::print("LINE line [" + line + "] func [" + fname + "]");
        ::print("file [" + srcfile + "]\n");
        break;
    }
}
```

The parameter *event_type* can be 'l', 'c' or 'r'; a hook with a 'l' event is called for each line that gets executed, 'c' every time a function gets called and 'r' every time a function returns.

A full-featured debugger always allows displaying local variables and calls stack. The call stack information are retrieved through `sq_getstackinfos()`:

```
SQInteger sq_stackinfos(HSQUIRRELVM v, SQInteger level, SQStackInfos *si);
```

While the local variables info through `sq_getlocal()`:

```
SQInteger sq_getlocal(HSQUIRRELVM v, SQUnsignedInteger level, SQUnsignedInteger nseq);
```

In order to receive line callbacks the scripts have to be compiled with debug infos enabled this is done through `sq_enableddebuginfo()`:

```
void sq_enableddebuginfo(HSQUIRRELVM v, SQInteger debuginfo);
```

4.1 Virtual Machine

void **sq_close** (HSQUIRRELV *v*)

Parameters

- *v* (*HSQUIRRELV*) – the target VM

releases a squirrel VM and all related friend VMs

SQPRINTFUNCTION **sq_geterrorfunc** (HSQUIRRELV *v*)

Parameters

- *v* (*HSQUIRRELV*) – the target VM

Returns a pointer to a SQPRINTFUNCTION, or NULL if no function has been set.

returns the current error function of the given Virtual machine. (see sq_setprintfunc())

SQUserPointer **sq_getforeignptr** (HSQUIRRELV *v*)

Parameters

- *v* (*HSQUIRRELV*) – the target VM

Returns the current VMs foreign pointer.

Returns the foreign pointer of a VM instance.

SQPRINTFUNCTION **sq_getprintfunc** (HSQUIRRELV *v*)

Parameters

- *v* (*HSQUIRRELV*) – the target VM

Returns a pointer to a SQPRINTFUNCTION, or NULL if no function has been set.

returns the current print function of the given Virtual machine. (see sq_setprintfunc())

SQUserPointer **sq_getsharedforeignptr** (HSQUIRRELV *v*)

Parameters

- *v* (*HSQUIRRELV*) – the target VM

Returns the current VMs shared foreign pointer

Returns the shared foreign pointer of a group of friend VMs

SQUserPointer **sq_getsharedreleasehook** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

Returns the current VMs release hook.

Returns the shared release hook of a group of friend VMs

SQInteger **sq_getversion** ()

Returns version number of the vm(as in SQUIRREL_VERSION_NUMBER).

returns the version number of the vm

SQUserPointer **sq_getvmreleasehook** (*HSQUIRRELVm v*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

Returns the current VMs release hook.

Returns the release hook of a VM instance

SQInteger **sq_getvmstate** (*HSQUIRRELVm v*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

Returns the state of the vm encoded as integer value. The following constants are defined: SQ_VMSTATE_IDLE, SQ_VMSTATE_RUNNING, SQ_VMSTATE_SUSPENDED.

returns the execution state of a virtual machine

void **sq_move** (*HSQUIRRELVm dest, HSQUIRRELVm src, SQInteger idx*)

Parameters

- **dest** (*HSQUIRRELVm*) – the destination VM
- **src** (*HSQUIRRELVm*) – the source VM
- **idx** (*SQInteger*) – the index in the source stack of the value that has to be moved

pushes the object at the position 'idx' of the source vm stack in the destination vm stack

HSQUIRRELVm **sq_newthread** (*HSQUIRRELVm friendvm, SQInteger initialstacksize*)

Parameters

- **friendvm** (*HSQUIRRELVm*) – a friend VM
- **initialstacksize** (*SQInteger*) – the size of the stack in slots(number of objects)

Returns a pointer to the new VM.

Remarks By default the roottable is shared with the VM passed as first parameter. The new VM lifetime is bound to the “thread” object pushed in the stack and behave like a normal squirrel object.

creates a new vm friendvm of the one passed as first parameter and pushes it in its stack as “thread” object.

HSQUIRRELVm **sq_open** (*SQInteger initialstacksize*)

Parameters

- **initialstacksize** (*SQInteger*) – the size of the stack in slots(number of objects)

Returns an handle to a squirrel vm

Remarks the returned VM has to be released with sq_releasevm

creates a new instance of a squirrel VM that consists in a new execution stack.

void **sq_pushconsttable** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

pushes the current const table in the stack

void **sq_pushregistrytable** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

pushes the registry table in the stack

void **sq_pushroottable** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

pushes the current root table in the stack

void **sq_setconsttable** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

pops a table from the stack and set it as const table

void **sq_seterrorhandler** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

Remarks the error handler is shared by friend VMs

pops from the stack a closure or native closure and sets it as runtime-error handler.

void **sq_setforeignptr** (HSQUIRRELV *v*, SQUintptr *p*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **p** (*SQUintptr*) – The pointer that has to be set

Sets the foreign pointer of a certain VM instance. The foreign pointer is an arbitrary user defined pointer associated to a VM (by default is value id 0). This pointer is ignored by the VM.

void **sq_setprintfunc** (HSQUIRRELV *v*, SQPRINTFUNCTION *printfunc*, SQPRINTFUNCTION *errorfunc*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **printfunc** (*SQPRINTFUNCTION*) – a pointer to the print func or NULL to disable the output.
- **errorfunc** (*SQPRINTFUNCTION*) – a pointer to the error func or NULL to disable the output.

Remarks the print func has the following prototype: void printfunc(HSQUIRRELV *v*, const SQChar **s*,...)

sets the print function of the virtual machine. This function is used by the built-in function ‘::print()’ to output text.

void **sq_setroottable** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

pops a table from the stack and set it as root table

void **sq_setsharedforeignptr** (HSQUIRRELV *v*, SQUserPointer *p*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **p** (*SQUserPointer*) – The pointer that has to be set

Sets the shared foreign pointer. The foreign pointer is an arbitrary user defined pointer associated to a group of friend VMs (by default is value id 0). After a “main” VM is created using `sq_open()` all friend VMs created with `sq_newthread` share the same shared pointer.

void **sq_setsharedreleasehook** (HSQUIRRELV *v*, SQRELEASEHOOK *hook*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **hook** (*SQRELEASEHOOK*) – The hook that has to be set

Sets the release hook of a certain VM group. The release hook is invoked when the last vm of the group vm is destroyed (usually when `sq_close()` is invoked). The userpointer passed to the function is the shared foreignpointer(see `sq_getsharedforeignptr()`). After a “main” VM is created using `sq_open()` all friend VMs created with `sq_newthread()` share the same shared release hook.

void **sq_setvmreleasehook** (HSQUIRRELV *v*, SQRELEASEHOOK *hook*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **hook** (*SQRELEASEHOOK*) – The hook that has to be set

Sets the release hook of a certain VM instance. The release hook is invoked when the vm is destroyed. The userpointer passed to the function is the vm foreignpointer (see `sq_setforeignpointer()`)

HRESULT **sq_suspendvm** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

Returns an SQRRESULT(that has to be returned by a C function)

Remarks `sq_result` can only be called as return expression of a C function. The function will fail is the suspension is done through more C calls or in a metamethod.

Suspends the execution of the specified vm.

.eg

```
SQInteger suspend_vm_example(HSQUIRRELV v)
{
    return sq_suspendvm(v);
}
```

HRESULT **sq_wakeupvm** (HSQUIRRELV *v*, SQBool *resumedret*, SQBool *retval*, SQBool *raiseerror*, SQBool *throwerror*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **resumedret** (*SQBool*) – if true the function will pop a value from the stack and use it as return value for the function that has previously suspended the virtual machine.
- **retval** (*SQBool*) – if true the function will push the return value of the function that suspend the execution or the main function one.
- **raiseerror** (*SQBool*) – if true, if a runtime error occurs during the execution of the call, the vm will invoke the error handler.
- **throwerror** (*SQBool*) – if true, the vm will throw an exception as soon as is resumed. the exception payload must be set beforehand invoking `sq_throwerror()`.

Returns an HRESULT.

wake up the execution a previously suspended virtual machine

4.2 Compiler

SQRESULT **sq_compile** (*HSQUIRRELVm v*, *HSQLEXREADFUNC read*, *SQUserPointer p*, *const SQChar * sourcename*, *SQBool raiseerror*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **read** (*HSQLEXREADFUNC*) – a pointer to a read function that will feed the compiler with the program.
- **p** (*SQUserPointer*) – a user defined pointer that will be passed by the compiler to the read function at each invocation.
- *** sourcename** (*SQChar*) – the symbolic name of the program (used only for more meaningful runtime errors)
- **raiseerror** (*SQBool*) – if this value is true the compiler error handler will be called in case of an error

Returns a SQRESULT. If the `sq_compile` fails nothing is pushed in the stack.

Remarks in case of an error the function will call the function set by `sq_setcompilererrorhandler()`.

compiles a squirrel program; if it succeeds, push the compiled script as function in the stack.

SQRESULT **sq_compilebuffer** (*HSQUIRRELVm v*, *const SQChar* s*, *SQInteger size*, *const SQChar * sourcename*, *SQBool raiseerror*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- *** s** (*SQChar*) – a pointer to the buffer that has to be compiled.
- **size** (*SQInteger*) – size in characters of the buffer passed in the parameter ‘s’.
- *** sourcename** (*SQChar*) – the symbolic name of the program (used only for more meaningful runtime errors)
- **raiseerror** (*SQBool*) – if this value true the compiler error handler will be called in case of an error

Returns a SQRESULT. If the `sq_compilebuffer` fails nothing is pushed in the stack.

Remarks in case of an error the function will call the function set by `sq_setcompilererrorhandler()`.
compiles a squirrel program from a memory buffer; if it succeeds, push the compiled script as function in the stack.
void `sq_enableddebuginfo` (HSQUIRRELV *v*, SQBool *enable*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **enable** (SQBool) – if true enables the debug info generation, if == 0 disables it.

Remarks The function affects all threads as well.

enable/disable the debug line information generation at compile time.

void `sq_notifyallexceptions` (HSQUIRRELV *v*, SQBool *enable*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **enable** (SQBool) – if true enables the error callback notification of handled exceptions.

Remarks By default the VM will invoke the error callback only if an exception is not handled (no try/catch traps are present in the call stack). If `notifyallexceptions` is enabled, the VM will call the error callback for any exception even if between try/catch blocks. This feature is useful for implementing debuggers.

enable/disable the error callback notification of handled exceptions.

void `sq_setcompilererrorhandler` (HSQUIRRELV *v*, SQCOMPILERERROR *f*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **f** (SQCOMPILERERROR) – A pointer to the error handler function

Remarks if the parameter *f* is NULL no function will be called when a compiler error occurs. The compiler error handler is shared between friend VMs.

sets the compiler error handler function

4.3 Stack Operations

SQInteger `sq_cmp` (HSQUIRRELV *v*)

Parameters

- **v** (HSQUIRRELV) – the target VM

Returns > 0 if obj1>obj2

Returns == 0 if obj1==obj2

Returns < 0 if obj1<obj2

compares 2 object from the top of the stack. obj2 should be pushed before obj1.

SQInteger `sq_gettop` (HSQUIRRELV *v*)

Parameters

- **v** (HSQUIRRELV) – the target VM

Returns an integer representing the index of the top of the stack

returns the index of the top of the stack

void **sq_pop** (HSQUIRRELV *v*, SQInteger *nelementstopop*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **nelementstopop** (SQInteger) – the number of elements to pop

pops *n* elements from the stack

void **sq_poptop** (HSQUIRRELV *v*)

Parameters

- **v** (HSQUIRRELV) – the target VM

pops 1 object from the stack

void **sq_push** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – the index in the stack of the value that has to be pushed

pushes in the stack the value at the index *idx*

void **sq_remove** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the element that has to be removed

removes an element from an arbitrary position in the stack

SQRESULT **sq_reservestack** (HSQUIRRELV *v*, SQInteger *nsiz*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **nsiz** (SQInteger) – required stack size

Returns a SQRESULT

ensure that the stack space left is at least of a specified size. If the stack is smaller it will automatically grow. If there's a metaclass currently running the function will fail and the stack will not be resized, this situation has to be considered a "stack overflow".

void **sq_settop** (HSQUIRRELV *v*, SQInteger *x*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **x** (SQInteger) – the new top index

resize the stack. If new top is bigger then the current top the function will push nulls.

4.4 Object creation and handling

SQRESULT **sq_bindenv** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target closure

Returns a SQRESULT

Remarks the cloned closure holds the environment object as weak reference

pops an object from the stack (must be a table, instance, or class); clones the closure at position *idx* in the stack and sets the popped object as environment of the cloned closure. Then pushes the new cloned closure on top of the stack.

SQRESULT **sq_createinstance** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target class

Returns a SQRESULT

Remarks the function doesn't invoke the instance constructor. To create an instance and automatically invoke its constructor, `sq_call` must be used instead.

creates an instance of the class at 'idx' position in the stack. The new class instance is pushed on top of the stack.

SQRESULT **sq_getbool** (HSQUIRRELV *v*, SQInteger *idx*, SQBool * *b*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- * **b** (*SQBool*) – A pointer to the bool that will store the value

Returns a SQRESULT

gets the value of the bool at the *idx* position in the stack.

SQRESULT **sq_getbyhandle** (HSQUIRRELV *v*, SQInteger *idx*, HSQMEMBERHANDLE * *handle*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack pointing to the class or instance
- * **handle** (*HSQMEMBERHANDLE*) – a pointer to the member handle

Returns a SQRESULT

pushes the value of a class or instance member using a member handle (see `sq_getmemberhandle`)

SQRESULT **sq_getclosureinfo** (HSQUIRRELV *v*, SQInteger *idx*, SQInteger * *nparams*, SQInteger * *nfreevars*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target closure

- *** nparams** (*SQInteger*) – a pointer to an integer that will store the number of parameters
- *** nfreevars** (*SQInteger*) – a pointer to an integer that will store the number of free variables

Returns an SQRESULT

retrieves number of parameters and number of freevariables from a squirrel closure.

SQRESULT **sq_getclosurename** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target closure

Returns an SQRESULT

pushes the name of the closure at position *idx* in the stack. Note that the name can be a string or null if the closure is anonymous or a native closure with no name assigned to it.

SQRESULT **sq_getclosureroot** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target closure

Returns an SQRESULT

pushes the root table of the closure at position *idx* in the stack

SQRESULT **sq_getfloat** (HSQUIRRELV *v*, SQInteger *idx*, SQFloat * *f*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- *** f** (*SQFloat*) – A pointer to the float that will store the value

Returns a SQRESULT

gets the value of the float at the *idx* position in the stack.

SQHash **sq_gethash** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack

Returns the hash key of the value at the position *idx* in the stack

Remarks the hash value function is the same used by the VM.

returns the hash key of a value at the *idx* position in the stack.

SQRESULT **sq_getinstanceup** (HSQUIRRELV *v*, SQInteger *idx*, SQUserPointer * *up*, SQUserPointer *typetag*, SQBool *throwerror*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack

- *** up** (*SQUserPointer*) – a pointer to the userpointer that will store the result
- **typetag** (*SQUserPointer*) – the typetag that has to be checked, if this value is set to 0 the typetag is ignored. :param SQBool throwerror: if SQTrue the function sets the last error string in case of failure

Returns a SQRRESULT

gets the userpointer of the class instance at position *idx* in the stack. if the parameter ‘typetag’ is different than 0, the function checks that the class or a base class of the instance is tagged with the specified tag; if not the function fails. If ‘typetag’ is 0 the function will ignore the tag check.

SQRRESULT **sq_getinteger** (*HSQUIRRELV* *v*, *SQInteger idx*, *SQInteger * i*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- *** i** (*SQInteger*) – A pointer to the integer that will store the value

Returns a SQRRESULT

gets the value of the integer at the *idx* position in the stack.

SQRRESULT **sq_getmemberhandle** (*HSQUIRRELV* *v*, *SQInteger idx*, *HSQMEMBERHANDLE * handle*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack pointing to the class
- *** handle** (*HSQMEMBERHANDLE*) – a pointer to the variable that will store the handle

Returns a SQRRESULT

Remarks This method works only with classes. A handle retrieved through a class can be later used to set or get values from one of the class instances. Handles retrieved from base classes are still valid in derived classes and respect inheritance rules.

pops a value from the stack and uses it as index to fetch the handle of a class member. The handle can be later used to set or get the member value using `sq_getbyhandle()`, `sq_setbyhandle()`.

SQRELEASEHOOK **sq_getreleasehook** (*HSQUIRRELV* *v*, *SQInteger idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack

Remarks if the object that position *idx* is not an userdata, class instance or class the function returns NULL.

gets the release hook of the userdata, class instance or class at position *idx* in the stack.

SQChar * **sq_getscratchpad** (*HSQUIRRELV* *v*, *SQInteger minsize*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **minsize** (*SQInteger*) – the requested size for the scratchpad buffer

Remarks the buffer is valid until the next call to `sq_getscratchpad`

returns a pointer to a memory buffer that is at least as big as minsize.

SQObjectType **sq_getsize** (HSQUIRRELVm *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – an index in the stack

Returns the size of the value at the position *idx* in the stack

Remarks this function only works with strings, arrays, tables, classes, instances, and userdata if the value is not a valid type, the function will return -1.

returns the size of a value at the *idx* position in the stack. If the value is a class or a class instance the size returned is the size of the userdata buffer (see `sq_setclassudsize`).

SQRESULT **sq_getstring** (HSQUIRRELVm *v*, SQInteger *idx*, const SQChar ** *c*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- ** **c** (*SQChar*) – a pointer to the pointer that will point to the string

Returns a SQRESULT

gets a pointer to the string at the *idx* position in the stack.

SQRESULT **sq_getstringandsize** (HSQUIRRELVm *v*, SQInteger *idx*, const SQChar ** *c*, SQInteger* *size*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- ** **c** (*SQChar*) – a pointer to the pointer that will point to the string
- * **size** (*SQInteger*) – a pointer to a SQInteger which will receive the size of the string

Returns a SQRESULT

gets a pointer to the string at the *idx* position in the stack; additionally retrieves its size.

SQRESULT **sq_getthread** (HSQUIRRELVm *v*, SQInteger *idx*, HSQUIRRELVm* *vm*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- * **vm** (*HSQUIRRELVm*) – A pointer to the variable that will store the thread pointer

Returns a SQRESULT

gets a pointer to the thread the *idx* position in the stack.

SQObjectType **sq_gettype** (HSQUIRRELVm *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – an index in the stack

Returns the type of the value at the position `idx` in the stack

returns the type of the value at the position `idx` in the stack

SQRESULT **sq_gettypetag** (HSQUIRRELV *v*, SQInteger *idx*, SQUserPointer * *typetag*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – an index in the stack
- * **typetag** (SQUserPointer) – a pointer to the variable that will store the tag

Returns a SQRESULT

Remarks the function works also with instances. if the target object is an instance, the typetag of it's base class is fetched.

gets the typetag of the object (userdata or class) at position `idx` in the stack.

SQRESULT **sq_getuserdata** (HSQUIRRELV *v*, SQInteger *idx*, SQUserPointer * *p*, SQUserPointer * *typetag*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – an index in the stack
- * **p** (SQUserPointer) – A pointer to the userpointer that will point to the userdata's payload
- * **typetag** (SQUserPointer) – A pointer to a SQUserPointer that will store the userdata tag (see `sq_settypetag`). The parameter can be NULL.

Returns a SQRESULT

gets a pointer to the value of the userdata at the `idx` position in the stack.

SQRESULT **sq_getuserpointer** (HSQUIRRELV *v*, SQInteger *idx*, SQUserPointer * *p*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – an index in the stack
- * **p** (SQUserPointer) – A pointer to the userpointer that will store the value

Returns a SQRESULT

gets the value of the userpointer at the `idx` position in the stack.

void **sq_newarray** (HSQUIRRELV *v*, SQInteger *size*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **size** (SQInteger) – the size of the array that as to be created

creates a new array and pushes it in the stack

SQRESULT **sq_newclass** (HSQUIRRELV *v*, SQBool *hasbase*)

Parameters

- **v** (HSQUIRRELV) – the target VM

- **hasbase** (*SQBool*) – if the parameter is true the function expects a base class on top of the stack.

Returns a *SQRESULT*

creates a new class object. If the parameter ‘hasbase’ is different than 0, the function pops a class from the stack and inherits the new created class from it. The new class is pushed in the stack.

void **sq_newclosure** (*HSQUIRRELV**m* *v*, *HSQFUNCTION* *func*, *SQInteger* *nfreevars*)

Parameters

- **v** (*HSQUIRRELV**m*) – the target VM
- **func** (*HSQFUNCTION*) – a pointer to a native-function
- **nfreevars** (*SQInteger*) – number of free variables(can be 0)

create a new native closure, pops n values set those as free variables of the new closure, and push the new closure in the stack.

void **sq_newtable** (*HSQUIRRELV**m* *v*)

Parameters

- **v** (*HSQUIRRELV**m*) – the target VM

creates a new table and pushes it in the stack

void **sq_newtableex** (*HSQUIRRELV**m* *v*, *SQInteger* *initialcapacity*)

Parameters

- **v** (*HSQUIRRELV**m*) – the target VM
- **initialcapacity** (*SQInteger*) – number of key/value pairs to preallocate

creates a new table and pushes it in the stack. This function allows you to specify the initial capacity of the table to prevent unnecessary rehashing when the number of slots required is known at creation-time.

SQUserPointer **sq_newuserdata** (*HSQUIRRELV**m* *v*, *SQUnsignedInteger* *size*)

Parameters

- **v** (*HSQUIRRELV**m*) – the target VM
- **size** (*SQUnsignedInteger*) – the size of the userdata that as to be created in bytes

creates a new userdata and pushes it in the stack

void **sq_pushbool** (*HSQUIRRELV**m* *v*, *SQBool* *b*)

Parameters

- **v** (*HSQUIRRELV**m*) – the target VM
- **b** (*SQBool*) – the bool that has to be pushed(SQTrue or SQFalse)

pushes a bool into the stack

void **sq_pushfloat** (*HSQUIRRELV**m* *v*, *SQFloat* *f*)

Parameters

- **v** (*HSQUIRRELV**m*) – the target VM
- **f** (*SQFloat*) – the float that has to be pushed

pushes a float into the stack

void **sq_pushinteger** (HSQUIRRELV *v*, SQInteger *n*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **n** (*SQInteger*) – the integer that has to be pushed

pushes an integer into the stack

void **sq_pushnull** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

pushes a null value into the stack

void **sq_pushstring** (HSQUIRRELV *v*, const SQChar * *s*, SQInteger *len*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- * **s** (*SQChar*) – pointer to the string that has to be pushed
- **len** (*SQInteger*) – length of the string pointed by *s*

Remarks if the parameter *len* is less than 0 the VM will calculate the length using `strlen(s)`

pushes a string in the stack

void **sq_pushuserpointer** (HSQUIRRELV *v*, SQUserPointer *p*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **p** (*SQUserPointer*) – the pointer that as to be pushed

pushes a userpointer into the stack

SQRESULT **sq_setbyhandle** (HSQUIRRELV *v*, SQInteger *idx*, HSQMEMBERHANDLE * *handle*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack pointing to the class
- * **handle** (*HSQMEMBERHANDLE*) – a pointer the member handle

Returns a SQRESULT

pops a value from the stack and sets it to a class or instance member using a member handle (see `sq_getmemberhandle`)

SQRESULT **sq_setclassudsize** (HSQUIRRELV *v*, SQInteger *idx*, SQInteger *udsize*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack pointing to the class
- **udsize** (*SQInteger*) – size in bytes reserved for user data

Returns a SQRESULT

Sets the user data size of a class. If a class ‘user data size’ is greater than 0. When an instance of the class is created additional space will be reserved at the end of the memory chunk where the instance is stored. The userpointer of the instance will also be automatically set to this memory area. This allows you to minimize allocations in applications that have to carry data along with the class instance.

SQRESULT **sq_setclosureroot** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target closure

Returns an SQRESULT

pops a table from the stack and sets it as root of the closure at position *idx* in the stack

SQRESULT **sq_setinstanceup** (HSQUIRRELV *v*, SQInteger *idx*, SQUserPointer *up*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- **up** (*SQUserPointer*) – an arbitrary user pointer

Returns a SQRESULT

sets the userpointer of the class instance at position *idx* in the stack.

SQRESULT **sq_setnativeclosurename** (HSQUIRRELV *v*, SQInteger *idx*, const SQChar * *name*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target native closure
- * **name** (*SQChar*) – the name that has to be set

Returns an SQRESULT

sets the name of the native closure at the position *idx* in the stack. The name of a native closure is purely for debug purposes. The name is retrieved through the function `sq_stackinfos()` while the closure is in the call stack.

SQRESULT **sq_setparamscheck** (HSQUIRRELV *v*, SQInteger *nparamscheck*, const SQChar * *typemask*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **nparamscheck** (*SQInteger*) – defines the parameters number check policy (0 disables the param checking). If *nparamscheck* is greater than 0, the VM ensures that the number of parameters is exactly the number specified in *nparamscheck* (eg. if *nparamscheck* == 3 the function can only be called with 3 parameters). If *nparamscheck* is less than 0 the VM ensures that the closure is called with at least the absolute value of the number specified in *nparamscheck* (eg. *nparamscheck* == -3 will check that the function is called with at least 3 parameters). The hidden parameter ‘this’ is included in this number; free variables aren’t. If `SQ_MATCHTYPEMASKSTRING` is passed instead of the number of parameters, the function will automatically infer the number of parameters to check from the typemask (eg. if the typemask is “.sn”, it is like passing 3).
- * **typemask** (*SQChar*) – defines a mask to validate the parameter types passed to the function. If the parameter is NULL, no typechecking is applied (default).

Remarks The typemask consists in a zero terminated string that represent the expected parameter type. The types are expressed as follows: ‘o’ null, ‘i’ integer, ‘f’ float, ‘n’ integer or float, ‘s’ string, ‘t’ table, ‘a’ array, ‘u’ userdata, ‘c’ closure and nativeclosure, ‘g’ generator, ‘p’ userpointer, ‘v’ thread, ‘x’ instance(class instance), ‘y’ class, ‘b’ bool. and ‘.’ any type. The symbol ‘|’ can be used as ‘or’ to accept multiple types on the same parameter. There isn’t any limit on the number of ‘or’ that can be used. Spaces are ignored so can be inserted between types to increase readability. For instance to check a function that expect a table as ‘this’ a string as first parameter and a number or a userpointer as second parameter, the string would be “tsn|p” (table,string,number or userpointer). If the parameters mask is contains fewer parameters than ‘nparamscheck’, the remaining parameters will not be typechecked.

Sets the parameter validation scheme for the native closure at the top position in the stack. Allows you to validate the number of parameters accepted by the function and optionally their types. If the function call does not comply with the parameter schema set by `sq_setparamscheck`, an exception is thrown.

.eg

```
//example
SQInteger testy(HSQIRRELVM v)
{
    SQUserPointer p;
    const SQChar *s;
    SQInteger i;
    //no type checking, if the call complies with the mask
    //surely the functions will succeed.
    sq_getuserdata(v,1,&p,NULL);
    sq_getstring(v,2,&s);
    sq_getinteger(v,3,&i);
    //... do something
    return 0;
}

//the reg code

//....stuff
sq_newclosure(v,testy,0);
//expects exactly 3 parameters(userdata,string,number)
sq_setparamscheck(v,3,_SC("usn"));
//....stuff
```

void **sq_setreleasehook** (HSQIRRELVM v, SQInteger idx, SQRELEASEHOOK hook)

Parameters

- **v** (HSQIRRELVM) – the target VM
- **idx** (SQInteger) – an index in the stack
- **hook** (SQRELEASEHOOK) – a function pointer to the hook(see sample below)

Remarks the function hook is called by the VM before the userdata memory is deleted.

sets the release hook of the userdata, class instance, or class at position idx in the stack.

.eg

```
/* tyedef SQInteger (*SQRELEASEHOOK) (SQUserPointer, SQInteger size); */
SQInteger my_release_hook(SQUserPointer p, SQInteger size)
{
```

(continues on next page)

(continued from previous page)

```

/* do something here */
return 1;
}

```

SQRESULT **sq_settypetag** (HSQUIRRELV *v*, SQInteger *idx*, SQUserPointer *typetag*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- **typetag** (*SQUserPointer*) – an arbitrary SQUserPointer

Returns a SQRESULT

sets the typetag of the object (userdata or class) at position *idx* in the stack.

void **sq_tobool** (HSQUIRRELV *v*, SQInteger *idx*, SQBool * *b*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack
- * **b** (*SQBool*) – A pointer to the bool that will store the value

Remarks if the object is not a bool the function converts the value to bool according to squirrel's rules. For instance the number 1 will result in true, and the number 0 in false.

gets the value at position *idx* in the stack as bool.

void **sq_tostring** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack

converts the object at position *idx* in the stack to string and pushes the resulting string in the stack.

SQObjectType **sq_typeof** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – an index in the stack

Returns a SQRESULT

pushes the type name of the value at the position *idx* in the stack. It also invokes the `_typeof` metamethod for tables and class instances that implement it; in that case the pushed object could be something other than a string (is up to the `_typeof` implementation).

4.5 Calls

SQRESULT **sq_call** (HSQUIRRELV *v*, SQInteger *params*, SQBool *retval*, SQBool *raiseerror*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

- **params** (*SQInteger*) – number of parameters of the function
- **retval** (*SQBool*) – if true the function will push the return value in the stack
- **raiseerror** (*SQBool*) – if true, if a runtime error occurs during the execution of the call, the vm will invoke the error handler.

Returns a *SQRESULT*

calls a closure or a native closure. The function pops all the parameters and leave the closure in the stack; if *retval* is true the return value of the closure is pushed. If the execution of the function is suspended through *sq_suspendvm()*, the closure and the arguments will not be automatically popped from the stack.

When using to create an instance, push a dummy parameter to be filled with the newly-created instance for the constructor's 'this' parameter.

SQRESULT **sq_getcallee** (*HSQUIRRELVm v*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

Returns a *SQRESULT*

push in the stack the currently running closure.

SQRESULT **sq_getlasterror** (*HSQUIRRELVm v*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

Returns a *SQRESULT*

Remarks the pushed error descriptor can be any valid squirrel type.

pushes the last error in the stack.

const *SQChar* * **sq_getlocal** (*HSQUIRRELVm v*, *SQUnsignedInteger level*, *SQUnsignedInteger nseq*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **level** (*SQUnsignedInteger*) – the function index in the calls stack, 0 is the current function
- **nseq** (*SQUnsignedInteger*) – the index of the local variable in the stack frame (0 is 'this')

Returns the name of the local variable if a variable exists at the given level/seq otherwise NULL.

Returns the name of a local variable given stackframe and sequence in the stack and pushes its current value. Free variables are treated as local variables, by *sq_getlocal()*, and will be returned as they would be at the base of the stack, just before the real local variables.

void **sq_reseterror** (*HSQUIRRELVm v*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

reset the last error in the virtual machine to null

SQRESULT **sq_resume** (*HSQUIRRELVm v*, *SQBool retval*, *SQBool raiseerror*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

- **retval** (*SQBool*) – if true the function will push the return value in the stack
- **raiseerror** (*SQBool*) – if true, if a runtime error occurs during the execution of the call, the vm will invoke the error handler.

Returns a *SQRESULT*

Remarks if `retval != 0` the return value of the generator is pushed.

resumes the generator at the top position of the stack.

SQRESULT **sq_tailcall** (*HSQUIRRELVm v*, *SQInteger nparams*)

param HSQUIRRELVm v the target VM

param SQInteger nparams number of parameters of the function

Calls a closure and removes the caller function from the call stack. This function must be invoked from a native closure and the return value of `sq_tailcall` must be returned by the caller function (see example).

.eg

```
SQInteger tailcall_something_example(HSQUIRRELVm v)
{
    //push closure and parameters here
    ...
    return sq_tailcall(v,2);
}
```

SQRESULT **sq_throwerror** (*HSQUIRRELVm v*, *const SQChar * err*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- *** err** (*SQChar*) – the description of the error that has to be thrown

Returns the value that has to be returned by a native closure in order to throw an exception in the virtual machine.

sets the last error in the virtual machine and returns the value that has to be returned by a native closure in order to trigger an exception in the virtual machine.

SQRESULT **sq_throwobject** (*HSQUIRRELVm v*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

Returns the value that has to be returned by a native closure in order to throw an exception in the virtual machine.

pops a value from the stack sets it as the last error in the virtual machine. Returns the value that has to be returned by a native closure in order to trigger an exception in the virtual machine (aka `SQ_ERROR`).

4.6 Object manipulation

SQRESULT **sq_arrayappend** (*HSQUIRRELVm v*, *SQInteger idx*)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – index of the target array in the stack

Returns a SQRESULT

Remarks Only works on arrays.

pops a value from the stack and pushes it in the back of the array at the position *idx* in the stack.

SQRESULT **sq_arrayinsert** (HSQUIRRELV *v*, SQInteger *idx*, SQInteger *destpos*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target array in the stack
- **destpos** (SQInteger) – the position in the array where the item has to be inserted

Returns a SQRESULT

Remarks Only works on arrays.

pops a value from the stack and inserts it in an array at the specified position

SQRESULT **sq_arraypop** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target array in the stack

Returns a SQRESULT

Remarks Only works on arrays.

pops a value from the back of the array at the position *idx* in the stack.

SQRESULT **sq_arrayremove** (HSQUIRRELV *v*, SQInteger *idx*, SQInteger *itemidx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target array in the stack
- **itemidx** (SQInteger) – the index of the item in the array that has to be removed

Returns a SQRESULT

Remarks Only works on arrays.

removes an item from an array

SQRESULT **sq_arrayresize** (HSQUIRRELV *v*, SQInteger *idx*, SQInteger *newsiz*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target array in the stack
- **newsiz** (SQInteger) – requested size of the array

Returns a SQRESULT

Remarks Only works on arrays. If *newsiz* is greater than the current size the new array slots will be filled with nulls.

resizes the array at the position *idx* in the stack.

SQRESULT **sq_arrayreverse** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELVM*) – the target VM
- **idx** (*SQInteger*) – index of the target array in the stack

Returns a *SQRESULT*

Remarks Only works on arrays.

reverses an array in place.

SQRESULT **sq_clear** (*HSQUIRRELVM v*, *SQInteger idx*)

Parameters

- **v** (*HSQUIRRELVM*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

Returns a *SQRESULT*

Remarks Only works on tables and arrays.

clears all the elements of the table/array at position *idx* in the stack.

SQRESULT **sq_clone** (*HSQUIRRELVM v*, *SQInteger idx*)

Parameters

- **v** (*HSQUIRRELVM*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

Returns a *SQRESULT*

pushes a clone of the table, array, or class instance at the position *idx*.

SQRESULT **sq_createslot** (*HSQUIRRELVM v*, *SQInteger idx*)

Parameters

- **v** (*HSQUIRRELVM*) – the target VM
- **idx** (*SQInteger*) – index of the target table in the stack

Returns a *SQRESULT*

Remarks invoke the `_newslot` metaclass in the table delegate. it only works on tables. [this function is deprecated since version 2.0.5 use `sq_newslot()` instead]

pops a key and a value from the stack and performs a set operation on the table or class that is at position *idx* in the stack; if the slot does not exist, it will be created.

SQRESULT **sq_deleteslot** (*HSQUIRRELVM v*, *SQInteger idx*, *SQBool pushval*)

Parameters

- **v** (*HSQUIRRELVM*) – the target VM
- **idx** (*SQInteger*) – index of the target table in the stack
- **pushval** (*SQBool*) – if this param is true the function will push the value of the deleted slot.

Returns a *SQRESULT*

Remarks invoke the `_delslot` metaclass in the table delegate. it only works on tables.

pops a key from the stack and delete the slot indexed by it from the table at position *idx* in the stack; if the slot does not exist, nothing happens.

SQRESULT **sq_get** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target object in the stack

Returns a SQRESULT

Remarks this call will invokes the delegation system like a normal dereference it only works on tables, arrays, classes, instances and userdata; if the function fails, nothing will be pushed in the stack.

pops a key from the stack and performs a get operation on the object at the position *idx* in the stack; and pushes the result in the stack.

SQRESULT **sq_getattributes** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target class in the stack

Returns a SQRESULT

Gets the attribute of a class member. The function pops a key from the stack and pushes the attribute of the class member indexed by they key from a class at position *idx* in the stack. If key is null the function gets the class level attribute.

SQRESULT **sq_getbase** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target class in the stack

Returns a SQRESULT

pushes the base class of the ‘class’ at stored position *idx* in the stack.

SQRESULT **sq_getclass** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target class instance in the stack

Returns a SQRESULT

pushes the class of the ‘class instance’ at stored position *idx* in the stack.

SQRESULT **sq_getdelegate** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (HSQUIRRELV) – the target VM
- **idx** (SQInteger) – index of the target object in the stack

Returns a SQRESULT

pushes the current delegate of the object at the position *idx* in the stack.

const SQChar * **sq_getfreevariable** (HSQUIRRELVm v, SQInteger idx, SQInteger nval)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack(closure)
- **nval** (*SQInteger*) – 0 based index of the free variable(relative to the closure).

Returns the name of the free variable for pure squirrel closures. NULL in case of error or if the index of the variable is out of range. In case the target closure is a native closure, the return name is always “@NATIVE”.

Remarks The function works for both squirrel closure and native closure.

gets the value of the free variable of the closure at the position idx in the stack.

SQRESULT **sq_getweakrefval** (HSQUIRRELVm v, SQInteger idx)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – index of the target weak reference

Returns a SQRESULT

Remarks if the function fails, nothing is pushed in the stack.

pushes the object pointed by the weak reference at position idx in the stack.

SQBool **sq_instanceof** (HSQUIRRELVm v)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM

Returns SQTrue if the instance at position -2 in the stack is an instance of the class object at position -1 in the stack.

Remarks The function doesn't pop any object from the stack.

Determines if an object is an instance of a certain class. Expects an instance and a class in the stack.

SQRESULT **sq_newmember** (HSQUIRRELVm v, SQInteger idx, SQBool bstatic)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – index of the target table in the stack
- **bstatic** (*SQBool*) – if SQTrue creates a static member.

Returns a SQRESULT

Remarks Invokes the `_newmember` metamethod in the class. it only works on classes.

pops a key, a value and an object (which will be set as attribute of the member) from the stack and performs a new slot operation on the class that is at position idx in the stack; if the slot does not exist, it will be created.

SQRESULT **sq_newslot** (HSQUIRRELVm v, SQInteger idx, SQBool bstatic)

Parameters

- **v** (*HSQUIRRELVm*) – the target VM
- **idx** (*SQInteger*) – index of the target table in the stack

- **bstatic** (*SQBool*) – if `SQTrue` creates a static member. This parameter is only used if the target object is a class.

Returns a `SQRESULT`

Remarks Invokes the `_newslot` metamethod in the table delegate. it only works on tables and classes.

pops a key and a value from the stack and performs a set operation on the table or class that is at position `idx` in the stack, if the slot does not exist it will be created.

`SQRESULT sq_next` (*HSQUIRRELV* *v*, *SQInteger idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

Returns a `SQRESULT`

Pushes in the stack the next key and value of an array, table, or class slot. To start the iteration this function expects a null value on top of the stack; at every call the function will substitute the null value with an iterator and push key and value of the container slot. Every iteration the application has to pop the previous key and value but leave the iterator(that is used as reference point for the next iteration). The function will fail when all slots have been iterated(see Tables and arrays manipulation).

`SQRESULT sq_rawdeleteslot` (*HSQUIRRELV* *v*, *SQInteger idx*, *SQBool pushval*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target table in the stack
- **pushval** (*SQBool*) – if this param is true the function will push the value of the deleted slot.

Returns a `SQRESULT`

Deletes a slot from a table without employing the `_delslot` metamethod. Pops a key from the stack and delete the slot indexed by it from the table at position `idx` in the stack; if the slot does not exist nothing happens.

`SQRESULT sq_rawget` (*HSQUIRRELV* *v*, *SQInteger idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

Returns a `SQRESULT`

Remarks Only works on tables and arrays.

pops a key from the stack and performs a get operation on the object at position `idx` in the stack, without employing delegation or metamethods.

`SQRESULT sq_rawnewmember` (*HSQUIRRELV* *v*, *SQInteger idx*, *SQBool bstatic*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target table in the stack
- **bstatic** (*SQBool*) – if `SQTrue` creates a static member.

Returns a `SQRESULT`

Remarks it only works on classes.

pops a key, a value and an object(that will be set as attribute of the member) from the stack and performs a new slot operation on the class that is at position *idx* in the stack; if the slot does not exist it will be created.

SQRESULT **sq_rawset** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

Returns a SQRESULT

Remarks it only works on tables and arrays. if the function fails nothing will be pushed in the stack.

pops a key and a value from the stack and performs a set operation on the object at position *idx* in the stack, without employing delegation or metamethods.

SQRESULT **sq_set** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

Returns a SQRESULT

Remarks this call will invoke the delegation system like a normal assignment, it only works on tables, arrays and userdata.

pops a key and a value from the stack and performs a set operation on the object at position *idx* in the stack.

SQRESULT **sq_setattributes** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target class in the stack.

Returns a SQRESULT

Sets the attribute of a class member. The function pops a key and a value from the stack and sets the attribute (indexed by the key) on the class at position *idx* in the stack. If key is null the function sets the class level attribute. If the function succeed, the old attribute value is pushed in the stack.

SQRESULT **sq_setdelegate** (HSQUIRRELV *v*, SQInteger *idx*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

Returns a SQRESULT

Remarks to remove the delegate from an object, set a null value.

pops a table from the stack and sets it as the delegate of the object at the position *idx* in the stack.

SQRESULT **sq_setfreevariable** (HSQUIRRELV *v*, SQInteger *idx*, SQInteger *nval*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack

- **nv**al (*SQInteger*) – 0 based index of the free variable(relative to the closure).

Returns a SQRESULT

pops a value from the stack and sets it as a free variable of the closure at the position *idx* in the stack.

void **sq_weakref** (*HSQUIRRELV*M *v*, *SQInteger* *idx*)

Parameters

- **v** (*HSQUIRRELV*M) – the target VM
- **idx** (*SQInteger*) – index to the target object in the stack

Returns a SQRESULT

Remarks if the object at *idx* position is one of (integer, float, bool, null), the object itself is pushed instead of a weak ref.

pushes a weak reference to the object at position *idx* in the stack.

4.7 Bytecode serialization

SQRESULT **sq_readclosure** (*HSQUIRRELV*M *v*, *SQREADFUNC* *readf*, *SQUserPointer* *up*)

Parameters

- **v** (*HSQUIRRELV*M) – the target VM
- **readf** (*SQREADFUNC*) – pointer to a read function that will be invoked by the vm during the serialization.
- **up** (*SQUserPointer*) – pointer that will be passed to each call to the read function

Returns a SQRESULT

serialize (read) a closure and pushes it on top of the stack, the source is user defined through a read callback.

SQRESULT **sq_writeclosure** (*HSQUIRRELV*M *v*, *SQWRITEFUNC* *writef*, *SQUserPointer* *up*)

Parameters

- **v** (*HSQUIRRELV*M) – the target VM
- **writef** (*SQWRITEFUNC*) – pointer to a write function that will be invoked by the vm during the serialization.
- **up** (*SQUserPointer*) – pointer that will be passed to each call to the write function

Returns a SQRESULT

Remarks closures with free variables cannot be serialized

serializes(writes) the closure on top of the stack, the destination is user defined through a write callback.

4.8 Raw object handling

void **sq_addrf** (*HSQUIRRELV*M *v*, *HSQOBJECT* * *po*)

Parameters

- **v** (*HSQUIRRELV*M) – the target VM
- * **po** (*HSQOBJECT*) – pointer to an object handler

adds a reference to an object handler.

SQRESULT **sq_getobjtypetag** (HSQOBJECT * *o*, SQUserPointer * *typetag*)

Parameters

- * **o** (*HSQOBJECT*) – pointer to an object handler
- * **typetag** (*SQUserPointer*) – a pointer to the variable that will store the tag

Returns a SQRESULT

Remarks the function works also with instances. if the target object is an instance, the typetag of it's base class is fetched.

gets the typetag of a raw object reference(userdata or class).

SQUnsignedInteger **sq_getrefcount** (HSQUIRRELV *v*, HSQOBJECT * *po*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- * **po** (*HSQOBJECT*) – object handler

returns the number of references of a given object.

SQRESULT **sq_getstackobj** (HSQUIRRELV *v*, SQInteger *idx*, HSQOBJECT * *po*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **idx** (*SQInteger*) – index of the target object in the stack
- * **po** (*HSQOBJECT*) – pointer to an object handler

Returns a SQRESULT

gets an object from the stack and stores it in a object handler.

SQBool **sq_objtobool** (HSQOBJECT * *po*)

Parameters

- * **po** (*HSQOBJECT*) – pointer to an object handler

Remarks If the object is not a bool will always return false.

return the bool value of a raw object reference.

SQFloat **sq_objtfloat** (HSQOBJECT * *po*)

Parameters

- * **po** (*HSQOBJECT*) – pointer to an object handler

Remarks If the object is an integer will convert it to float. If the object is not a number will always return 0.

return the float value of a raw object reference.

SQInteger **sq_objtinteger** (HSQOBJECT * *po*)

Parameters

- * **po** (*HSQOBJECT*) – pointer to an object handler

Remarks If the object is a float will convert it to integer. If the object is not a number will always return 0.

return the integer value of a raw object reference.

const SQChar* **sq_objtostring** (HSQOBJECT * *po*)

Parameters

- * **po** (*HSQOBJECT*) – pointer to an object handler

Remarks If the object doesn't reference a string it returns NULL.

return the string value of a raw object reference.

SQUserPointer **sq_objtouserpointer** (HSQOBJECT * *po*)

Parameters

- * **po** (*HSQOBJECT*) – pointer to an object handler

Remarks If the object doesn't reference a userpointer it returns NULL.

return the userpointer value of a raw object reference.

void **sq_pushobject** (HSQUIRRELV *v*, HSQOBJECT *obj*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **obj** (*HSQOBJECT*) – object handler

push an object referenced by an object handler into the stack.

SQBool **sq_release** (HSQUIRRELV *v*, HSQOBJECT * *po*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- * **po** (*HSQOBJECT*) – pointer to an object handler

Returns SQTrue if the object handler released has lost all its references (the ones added with `sq_addrf`). SQFalse otherwise.

Remarks the function will reset the object handler to null when it loses all references.

remove a reference from an object handler.

void **sq_resetobject** (HSQOBJECT * *po*)

Parameters

- * **po** (*HSQOBJECT*) – pointer to an object handler

Remarks Every object handler has to be initialized with this function.

resets(initialize) an object handler.

4.9 Garbage Collector

SQInteger **sq_collectgarbage** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

Remarks this api only works with garbage collector builds (NO_GARBAGE_COLLECTOR is not defined)

runs the garbage collector and returns the number of reference cycles found (and deleted)

SQRESULT **sq_resurrectunreachable** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

Remarks this api only works with garbage collector builds (NO_GARBAGE_COLLECTOR is not defined)

runs the garbage collector and pushes an array in the stack containing all unreachable object found. If no unreachable object is found, null is pushed instead. This function is meant to help debug reference cycles.

4.10 Debug interface

SQRESULT **sq_getfunctioninfo** (HSQUIRRELV *v*, SQInteger *level*, SQFunctionInfo * *fi*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **level** (*SQInteger*) – calls stack level
- * **fi** (*SQFunctionInfo*) – pointer to the SQFunctionInfo structure that will store the closure informations

Returns a SQRESULT.

Remarks the member ‘funcid’ of the returned SQFunctionInfo structure is a unique identifier of the function; this can be useful to identify a specific piece of squirrel code in an application like for instance a profiler. this method will fail if the closure in the stack is a native C closure.

.eg

```
typedef struct tagSQFunctionInfo {
    SQUserPointer funcid; //unique idetifier for a function (all it's closures will
    ↪share the same funcid)
    const SQChar *name; //function name
    const SQChar *source; //function source file name
}SQFunctionInfo;
```

void **sq_setdebughook** (HSQUIRRELV *v*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM

Remarks In order to receive a ‘per line’ callback, is necessary to compile the scripts with the line informations. Without line informations activated, only the ‘call/return’ callbacks will be invoked.

pops a closure from the stack an sets it as debug hook. When a debug hook is set it overrides any previously set native or non native hooks. if the hook is null the debug hook will be disabled.

void **sq_setnatividebughook** (HSQUIRRELV *v*, SQDEBUGHOOK *hook*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **hook** (*SQDEBUGHOOK*) – the native hook function

Remarks In order to receive a ‘per line’ callback, is necessary to compile the scripts with the line informations. Without line informations activated, only the ‘call/return’ callbacks will be invoked.

sets the native debug hook. When a native hook is set it overrides any previously set native or non native hooks. if the hook is NULL the debug hook will be disabled.

SQRESULT **sq_stackinfos** (HSQUIRRELV *v*, SQInteger *level*, SQStackInfos * *si*)

Parameters

- **v** (*HSQUIRRELV*) – the target VM
- **level** (*SQInteger*) – calls stack level
- * **si** (*SQStackInfos*) – pointer to the SQStackInfos structure that will store the stack informations

Returns a SQRESULT.

retrieve the calls stack informations of a cerertain level in the calls stack.
